# Reducing Nonresponse Bias through Responsive Design and External Benchmarks 

Julia Lee<br>University of Michigan<br>July 17, 2012

Thesis committee: S. Heeringa, R. Little, T. Raghunathan, R. Valliant

## Goals of the Project

(1) To improve respondent representativeness
(2) To assess the nature of nonresponse
(3) To adjust for nonresponse

## Outline

- Introduction
- The proposed method
- Simulation results
- Next steps

## Current Practice

Reduce nonresponse bias at the analysis stage:

- Weighting class methods
- Propensity score methods
- Calibration
- (Imputation)

Challenges:

- Need nonrespondent information
- Assume ignorable nonresponse pattern
- Extreme and highly variable weights occur

## Alternatives

Reduce nonresponse bias at the design and data collection stages:

- Actively control for nonresponse bias at design stage by adaptively improving respondent representativeness.
- Effectively use frame data, contextual data, paradata, and benchmark information to obviate the need for nonrespondent information.

## Responsive Design Procedure

Objectives:

- Obviate the need for nonrespondent information
- Obtain more representative respondent pool

Terminology:

- Benchmark survey: capture desired target population, such as American Community Survey
- Current Survey: survey that you are conducting

## Responsive Design Procedure

Setting: Surveys with multi-phase data collection
The procedures:
(1) Complete first phase of data collection.
(2) Combine with benchmark information.
(3) Augument with frame data, contextual data, and paradata.
(9) Model the origin of each data point ( $1=$ benchmark, $0=$ current survey) in terms of covariates.
(3) Compute ratio of propensity score density $\left(R_{p s}\right)$ between benchmark and current survey.
(0) Sample next phase subjects using $R_{p s}$.
(3) Iterate steps 2 through 6 until acceptable representativeness or budget reached.

## The problem

How do we know propensity scores of next phase subjects before they respond?

## Data structure

|  |  | Y1 | Y2 | Y3 | Y4 | X1 | X2 | X3 | Z1 | Z2 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Bench | 1 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| Bench | 1 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| Bench | 1 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| $\ldots$ | 1 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S1 | 0 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S1 | 0 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| ... | 0 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |

| S2 | 0 |  |  |  |  | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S2 | 0 |  | d |  |  | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| $\cdots$ | 0 |  |  |  |  | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |

## Notation:

Ys are survey variables
Xs are common covariates across benchmark survey and the sample survey.
Zs are auxiliary data or contextual data from frame, registry, or interview observations, etc.

## The key step 1: Imputation

## Estimate propensity score of next samples using imputed covariates

|  |  | Y1 | Y2 | Y3 | Y4 | X1 | X2 | X3 | Z1 | Z2 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Bench | 1 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| Bench | 1 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |

| ... | 1 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S1 | 0 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S1 | 0 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| ... | 0 | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S2 | 0 | $\Delta$ | $\triangle$ | $\Delta$ | $\triangle$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S2 | 0 | $\text { maputation } \frac{\wedge}{4}$ |  |  |  | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S2 | 0 |  |  |  |  | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| S2 | 0 | $\Delta$ | $\triangle$ | $\Delta$ | $\wedge$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |
| $\ldots$ | 0 | $\triangle$ | $\triangle$ | $\Delta$ | - | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ | $\checkmark$ |

## Notation:

Ys are survey variables
Xs are common covariates across benchmark survey and the sample survey.
Zs are auxiliary data or contextual data from frame, registry, or interview observations, etc.

## The key step 2: $R_{p s}$

Define an acceptance/rejection process on the original sampling frame, to reduce or eliminate bias relative to the benchmark survey. Must satisfy:

$$
\pi P(Z \mid \text { accept })+(1-\pi) P(Z)=P_{B}(Z)
$$

where $\pi$ is the fraction of the combined data that are newly drawn.

What we want is $P($ accept $\mid Z)$. Choose $P(Z)$ to be propensity score density and use Bayes Theorem to obtain

$$
P(\text { accept } \mid Z) \propto \frac{P_{B}(Z)}{P(Z)}
$$

## NHIS vs BRFSS: Covariates in the propensity score model

The usual suspects:

- Geographic region
- Demographic: gender, age, race, marital status,
- Socio-economic status: education, income categories, work status

## Model fit and similarity measures

- Model fit diagnostics
- Distance measure on densities
- Hellinger distance to quantify the similarity between two probability distributions

$$
H^{2}=\frac{1}{2} \int(\sqrt{d P}-\sqrt{d Q})^{2}
$$

where $P$ and $Q$ represent the propensity score density from benchmark and current survey, respectively.

- Balance measure on covariates
- Absolute distance

## Thank you!
