## The September Review

Our lead article this month discusses two highly robust entities: health care and the Big Apple. For some years now, employment in health care industries in the United States has grown more rapidly than overall employment. In New York City, the same pattern has held. From 1990 through 2008, as noted by BLS economist Martin Kohli, health care employment grew by almost 42 percent, compared with 6.4 percent for total employment. In fact, during that period health care industries accounted for more than half of the quarter million jobs gained in the New York metropolitan area. This marked growth largely reflected an increase in the elderly population, a large supply of workers, and growing use of home health care; the latter industry, notably, "was the real jobs machine in New York City for years 2002 through 2008, adding more than 24,700 jobs."
The MLR has published a number of articles with a regional flavor. We continue the pattern this month with a focus on employment growth in the Kansas City metropolitan area, courtesy of BLS economists Jacqueline Michael-Midkiff, Linda Nickisch, and Cassandra Yocum. Over the past couple of decades, the authors report, there was a noteworthy narrowing of the gap between the higher level of employment on the Missouri side of the

Kansas City metropolitan area and the lower level of employment on the Kansas side. (The Metropolitan Statistical Area, or MSA, definition of the Kansas City area is nine counties in Missouri and six in Kansas.) Leading the shift was robust jobs growth in the Kansas county of Johnson, which over the period was responsible for more than 90 percent of the growth in the Kansas portion of the area. Johnson County still ranks second to Jackson County, Missouri, in total employment in the MSA, but it added the largest number of jobs from 1990 to 2007.
In the winter of 1959-60, according to BLS economist John F. Buckley, BLS conducted its first survey specifically designed to compare salaries of white-collar workers in private industry with the salaries established in the Federal General Schedule grade levels that covered a large majority of Federal white-collar workers. That survey, undertaken at the behest of the forerunners of today's Office of Management and Budget and Office of Personnel Management, was the Bureau's first to be used in the Federal pay-setting process. The history of BLS' contributions to that process is described in the article "Fifty Years of BLS surveys on Federal employees' pay," which rounds out this issue. The agency, as Buckley concludes, continues to work with "the Federal pay community to carry out its commitment to produce accurate and
timely data for policymakers and other users. The wage and salary information that the BLS collects is part of its broader measures of compensation that includes detailed information on employee nonwage benefits."

## 2008 Klein Awards

The Trustees of the Lawrence R. Klein Award announced the winners of the 2008 awards. This year one BLS-authored Monthly Labor Review article was recognized, "Business Processes and Business Functions: a new way of looking at employment." This article, by Sharon P. Brown, appeared in our December 2008 issue. Among authors contributing submissions from outside of BLS, Wen-Jui Han, Christopher J.Ruhm, Jane Waldfogel, and Elizabeth Washbrook were recognized for "The timing of mothers' employment after childbirth," which was published in the June issue.
Each year since 1969, the Lawrence R. Klein Award has honored the best articles appearing in the Review. The award was established in honor of Lawrence R. Klein, who retired in 1968 after 22 years as editor-in-chief of the Review and established a fund to encourage articles that (1) exhibit originality of ideas or methods or analysis, (2) adhere to the principles of scientific inquiry, and (3) are well written.

# Health care industries and the New York City labor market 

From 1990 to 1995, New York City's health care employment rose faster than the national average, but growth then slowed until 2002, when the pace quickened again; the 1995-2002 slowdown reflected slower growth in hospital care expenditures, while accelerated job growth after 2002 reflected strong growth in the elderly population and in home health care

Martin Kohli is the regional economist, New York Regional Office for Economic Analysis and Information, Bureau of Labor Statistics, New York, New York. E-mail: kohli.martin@bls.gov

In the United States, employment in the health care industries has grown more rapidly than total nonfarm employment. ${ }^{1}$ From 1990 through 2008, for instance, annual average total employment increased by 25.2 percent, while in health care the percent change was an even more robust 58.3 percent.
In New York City, the same pattern has held: total employment rose by 6.4 percent over the same 18 -year period, while health care employment expanded by 41.5 percent. Moreover, because industries other than health care have grown much more slowly in New York City than in the rest of the country, health care industries accounted for 52.1 percent of the 226,600 jobs gained during those years. As chart 1 shows, total employment in all industries combined, other than health care, declined relative to 1990 in 14 of the next 18 years. (For the purposes of this article, health care consists of three private-sector industries-ambulatory care (NAICS 621), hospitals (622), and nursing and residential care facilities (623)-and State government hospitals. ${ }^{2}$ This breakdown includes all private-sector employment in health care industries. Current employment data for Federal and local government hospitals in New York City are not available. An appendix discusses the sources and concepts of the labor market information used in this article.)

## Health care employment growth

Although health care employment has grown at a robust rate in New York City and the Nation, the pace has varied over time. From 1990 through 1995, employment in New York City's health care industries increased by at least 2.0 percent per year. Over the next 6 years, however, health care employment growth crossed that threshold only once. In 2002 employment growth rebounded, and in 4 of the years of the 2002-08 period growth again reached 2.0 percent. As chart 2 illustrates, employment growth in the national industry group followed the same pattern of decelerating in the later 1990s and then accelerating during the first half of the next decade. ${ }^{3}$ As table 1 shows, over the entire 18 -year period the average annual rate of employment change in the health care industries in New York City, 1.8 percent, although impressive, was lower than the national rate of 2.4 percent. But over the 1990-95 subperiod, the figures were closer: 3.0 percent in New York City and 3.3 percent in the Nation. Over the next 7 years, the gap widened, with health care employment in New York City increasing by an average of 1.4 percent per year while the national increases were 2.0 percent.
This article explores how health care industries in New York City first came close

## Chart 1. Indexes of annual average employment, health care industries and all industries other than health care,

 New York City, 1990-2008

ous year to the year shown. That is, for 1991, the over-the-year change is from 1990 to 1991; for 1992, the over-the-year change is from 1991 to 1992;

[^0]to matching the national pace of employment growth and then lagged behind. The starting point of the analysis is the fact that the aggregate of health care industries includes detailed industries that face different patterns of demand growth and different constraints in the labor market. The primary analytical question is whether New York City's slower growth in health care employment in the years after 1995 was a result of the mix of health care industries in the City, slower growth within detailed industries, or a combination of the two. Other studies of regional economies have used similar decompositions of employment growth. ${ }^{4}$
To be more specific about the issue of industry composition, consider that in 1990 private hospitals accounted for
the largest share of industry employment nationally, 40.7 percent, followed by ambulatory care. (See chart 3.) Private hospitals also were the largest health care employer in New York City, but the employment share in the City was 9.7 percentage points higher than it was nationally. In the mid- and late 1990 s, a number of initiatives, discussed later, aimed to slow the rate of growth of spending on hospital care. To the extent that these initiatives diminished the growth of hospital employment, industry composition could account for the sharper deceleration in New York City in 1996 and later years.
Before the aforementioned decomposition is presented, the next section considers factors influencing the growth of industry revenues in the years after 1990. Some of

Table 1. Employment in health care industries, United States and New York, 1990 and 2008

## Chart 3. Employment shares within health care industries, United States and New York City, 1990

[^1]these factors, such as the growth of the elderly population, influenced the growth of all health care industries, while other factors-namely, initiatives aimed at limiting the growth of spending for in-patient hospital care-were focused on particular industries within health care. A review of the factors influencing revenue growth, along with a brief review of labor market developments, will provide a context for interpreting the results of the decomposition.

## Factors influencing industry revenue growth

Money matters! One of the earlier mentioned studies of health care employment found that when funding was expanded or curtailed, employment trends changed. ${ }^{5}$ The most comprehensive information on health care spending, from the Centers for Medicare and Medicaid Services, is available for States, but not for cities. One of the issues this section explores is whether spending has expanded relatively more rapidly in the Nation or in New York State. Because health care spending tends to vary with the size of the population (as well as with other factors), the section begins by considering population growth in the Nation and in New York, the latter at both the State and sub-State levels.

Population growth. The population of the United States increased by 52 million between 1990 and 2007, an average of 1.1 percent a year. ${ }^{6}$ (See table 2.) The rate of change declined slightly over this period. From 1990 through 1995, the average rate of growth of the population was 1.3 percent per year. In the late 1990s and the early 2000s, the rate of growth eased downwards, but remained at or
above 0.9 percent, as chart 4 illustrates.
New York State's population expanded by 1.3 million from 1990 through 2007, a rate of 0.4 percent a year, less than the national rate. New York City's population grew by an average of 0.8 percent a year-less than the average growth rate for the Nation, but 4 times the average rate for the rest of New York State. Moreover, for all three subperiods examined (1990-95, 1995-2002, and 200207), the rate of change in the Nation exceeded the rate for New York City, which in turn exceeded the rest of the State's rate. (The years 1995 and 2002 were selected as midpoints because, as discussed earlier, health care employment growth decelerated beginning in 1995 and then accelerated starting in 2002.)
The aging of the population also contributes to the growth of health care industry revenues. Because of Medicare, the portion of the population without health insurance is lower for those older than 65 years than for the population as a whole. ${ }^{7}$ Because aging often leads to multiple medical problems, the elderly are more intense users of certain medical services. The elderly who are no longer able to take care of themselves are the primary customers of the nursing home and home health care industries. As a result of their greater access to insurance and their higher rates of utilization, medical spending for those older than 65 has tended to be at least twice as high as the average for all age groups. ${ }^{8}$ Thus, if New York City's elderly population had grown rapidly, that growth would be a possible explanation for the relatively strong employment growth of the City's health care industries during either the 1990-95 period or the 2002-08 period.
Nationally, the number of people aged 65 years and older increased by 6.6 million from 1990 through 2007,

with unrounded figures.

# Chart 4. Over-the-year changes in population, all ages, United States, New York City, and balance of New York State, 

 1990-2007
an average of 1.0 percent a year. During 1990-95, changes were at or above 1.3 percent per year, somewhat higher than the growth rate of the general population. The rate of change dipped toward the end of the decade and then rose again, reaching 1.7 percent in 2007.
The number of people aged 65 years and older in New York State increased by 0.2 million over the 18 -year period studied. The balance of the State had a larger numeric increase than the City did. The difference between the two areas was sharpest during the period 1990-95, when the number of elderly in New York City shrank. The losses ended in 1998. It follows that changes in the elderly population could not have contributed to the expansion of the City's health care industry during the 1990-95 period. Starting in 1999 and continuing through 2007, the number of elderly in New York City increased by at least 0.9 percent per year. From 1999 to 2004, the City's percentage increase exceeded the Nation's. (See chart 5.) These figures suggest that spending for the elderly might have contributed to the strong expansion of the City's health care industry during the 2002-08 period.

Personal health care spending and initiatives to control it. Information on health care spending, as measured by the Centers for Medicare and Medicaid Services, is for States,
but not for cities. At the State level, the Centers track spending on personal health care expenses (hospital care, professional services, nursing home and home health, and retail outlet sales-mostly for pharmaceuticals). Because population is a real (as opposed to a nominal) variable, the figures in table 3 reflect changes in spending, adjusted for changes in prices. ${ }^{9}$
Table 3 indicates how the growth of health care spending reflected demographic trends as well as other factors. Given the Nation's higher rates of population growth, it is not surprising that personal health care expenditures grew more rapidly in the United States than in New York State over the whole 1990-2004 period.
The years 1990-95, however, saw a larger rate of spending growth in New York State ( 1.5 percent per year) than in the Nation ( 0.9 percent). This difference was not due to either of the major public-sector programs: the average increases in New York State's Medicare and Medicaid spending were 0.3 percentage point and 1.5 percentage points smaller, respectively, than the national rates of growth over the subperiod. Over the next 7 years, however, national personal health care expenditures increased by an average of 0.8 percentage point per year more than New York State's expenditures. In the final subperiod shown in table 3, spending increased by an average of roughly 3

| Medicaid............................. | 8.4 | 11.1 | 13.4 | 13.8 | - | 3.0 | 5.2 | 2.3 | 1.7 |

NOTE: Medicaid amounts include Federal, State, and local dollars. Dashes indicate data not available. The most recent State-level data extend only to 2004. Components of personal health care expenditures were deflated with the use of the Consumer Price Indexes for hospital and related services, professional services, prescription drugs, nonprescription drugs, and medical services and the Producer Price Index for home health care services. All of these indexes
refer to the United States. December 1986 was used as a base because the Consumer Price Index for nonprescription drugs began in that month. Rates of change were calculated from unrounded expenditures.

SOURCE: Current-dollar expenditures are from the Centers for Medicare and Medicaid Services, Office of the Actuary.
percent a year in both the Nation and New York State.
Real spending by the two major Government programs did not adhere to the same patterns over time as did spending from all sources. In the first half of the 1990s, spending for Medicare and Medicaid was expanding more rapidly than spending from all sources in both the Nation and the State. After 1995, however, spending growth
for both programs decelerated. Part of the slowdown in Medicare can be attributed to slower growth in the number of people eligible for the program. As noted earlier, from 1990 through 1995 the number of people aged 65 years or older in the Nation increased by at least 1.3 percent a year, while in the late 1990s and the first part of the new decade the yearly increases were 1.0 percent or less.

The Balanced Budget Act of 1997 also contributed to the deceleration in Medicare spending. The Act reduced reimbursement rates for hospitals and established managed care alternatives to fee-for-service Medicare plans and new payment systems for home health services. ${ }^{10}$ In current dollars, Medicare spending on personal health care inched up 0.7 percent between 1997 and 1999, but spending for hospitals was little changed ( 0.1 percent), while expenditures for home health care plummeted 40.9 percent. ${ }^{11}$ In real terms, national Medicare spending on personal health care fell 5.4 percent between 1997 and 1999. Also, in 1997 Medicare began a demonstration project with 41 teaching hospitals, most of them in New York City, intended to reduce the program's future payments for graduate medical education. ${ }^{12}$
Medicare spending grew more slowly in New York State than in the Nation during all three subperiods. In part, this slower growth reflected that of the elderly population in the State.
The Balanced Budget Refinement Act, passed in November 1999, ameliorated the effects of the Balanced Budget Act. The later Act provided hospitals with additional funds for graduate medical education and reduced the cuts in Medicare payments to hospitals with a disproportionate share of indigent patients. The Act also postponed scheduled reductions in payments for home health care, while it increased payments to nursing homes for very sick patients. ${ }^{13}$ The Medicare Prescription Drug, Improvement, and Modernization Act of 2003 raised payments for managed care plans and rural providers in 2004. ${ }^{14}$ In part because of this Act, real Medicare expenditures increased 4.8 percent from 2003 to 2004.
Medicaid spending for the Nation displayed a similar pattern of slowing in the mid-1990s and then accelerating after 1998. Katharine Levit and her colleagues attributed the deceleration of nominal spending to a rise in managed care penetration, which went from 9.5 percent of Medicaid enrollment in fiscal year 1991 to 47.8 percent in fiscal year 1997. Also, the number of Medicaid enrollees dropped slightly in 1995 and 1996 and more markedly in 1997. ${ }^{15}$ In 1999, however, enrollment in the State Children's Health Insurance Program (SCHIP) more than doubled. ${ }^{16}$ SCHIP was a State-Federal program that allowed States to cover eligible children either through State-specific expansions or through expansions of existing Medicaid programs. Outreach efforts by State governments resulted in continued increases in enrollment in SCHIP and other Medicaid programs in the first years of the next decade. ${ }^{17}$
Several other developments influenced spending in New York State. In 1997, the State passed its Health Care

Reform Act, which ended a system of price regulation for State hospitals. At the time, occupancy rates were falling as the effects of the AIDS and other epidemics subsided. ${ }^{18}$ Although the deregulation of hospital rates was intended to encourage competition, some observers maintain that it helped trigger a round of mergers and consolidations in New York City that resulted in four networks of hospitals, centered around teaching hospitals and their medical schools. ${ }^{19}$ At the State level, Medicaid spending on personal health care fell 2.5 percent in real terms between 1996 and 1997, the only decline between 1990 and 2003. For hospitals in New York State, the decline in real Medicaid spending was even sharper: a 7.8 -percent drop between 1996 and 1997.
Figures from the New York State Department of Health show how different regions of the State were affected by changes in Medicaid spending. In both New York City and the rest of the State, Medicaid spending rose from 1990 until 1996. From 1996 to 1997, spending fell sharply in real terms. As chart 6 shows, New York City and the balance of the State experienced declines of similar magnitudes: 7.5 percent and 8.5 percent, respectively. Relatively slow spending growth characterized 1999 and 2000, but Medicaid spending expanded by between 4 percent and 9 percent a year in both the City and the rest of the State from 2001 through 2003.

## Occupational employment and education

Changes in health care spending are one influence on the demand for those who work in health care industries. A second set of influences reflects the specific skills and educational requirements of different industries within health care. Although certain occupations, such as registered nurse, are employed in significant numbers throughout the health care industries, other occupations tend to be concentrated within one of the detailed industries. Thus, supplies (or the lack) of different types of labor can help (or hinder) the expansion of particular health care industries.
Table 4 presents employment and annual wages for occupations with 1,000 or more jobs in health care industries in New York City in May 2007; the table's totals reflect all occupations, including those with fewer than 1,000 jobs. The self-employed were excluded. The table also identifies, for each occupation, the level of education or training generally required or attained by people in that occupation. ${ }^{20}$
More than 25,400 jobs (or 6.8 percent of employment) required a first professional degree; 16,010 of these were physicians and surgeons, all other (Standard Occupational

Classification code 29-1069), who are among the most educated workers. An additional 114,960 jobs required an associate's or higher degree; 49,100 of these jobs were as registered nurses, the most common occupation in the health care industries in New York City. Seventy percent of these nurses were in private hospitals, while 19 percent worked in ambulatory care and 8 percent in nursing homes. Within private hospitals, registered nurse was the detailed occupation with the most employment.
Another 12.8 percent of employment generally required postsecondary vocational awards; within this category, nursing aides, orderlies, and attendants, as well as licensed practical and licensed vocational nurses, with 31,040 and 10,010 jobs, respectively, accounted for large shares of employment. Approximately half of the nursing aides worked in the nursing home industry, where they were the detailed occupation with the greatest employment.
Finally, 110,560 jobs (or 29.4 percent of industry employment) required only short-term on-the-job training; of these jobs, 37,720 were as home health aides, the second most common occupation in the large industry group and the most common occupation in ambulatory care. Two clerical occupations-receptionists and information
clerks, and general office clerks-together accounted for another 22,850 jobs within the educational category of short-term on-the-job training.
Given the diversity of educational requirements, it is not surprising that these health care jobs pay at a variety of different wage and salary levels. More than 35,000 jobs ( 9.3 percent of employment) had a mean annual salary above $\$ 100,000$; of the occupations with more than 1,000 jobs, family and general practitioners, general dentists, and physicians and surgeons were among the highest paid. An additional 84,810 jobs had an average wage exceeding New York City's average of $\$ 54,140$. Home health aides, with an average of $\$ 18,421$, were the lowest paid workers.

## New York City labor market developments

The demand by health care industries for workers with specific educational credentials is only one factor in New York's City's large and dynamic labor market. The supply of labor-reflecting the growth of the population and decisions about education and participation-also matters. In addition to seeking certain skills, a number of managers in health care industries are concerned with the

SOURCES: Employment and wages are based on data provided by the New York State Department of Labor for ambulatory health care services, hospitals, and nursing and residential care facilities (NAICS 621-623) in the private sector and in State government hospitals. The classification of occupations by significant source of education was developed by the Bureau of Labor Statistics.
racial and ethnic diversity of the health care workforce. A recent report linked the issue of labor force diversity to the need to provide "culturally and linguistically appropriate care for New York's populations." ${ }^{21}$

Labor market constraints and opportunities. Historically, New York City has had a labor force participation rate below that of the Nation. In 1990, for example, 66.5 percent of the national population 16 years and older was either employed or unemployed, while in New York City the figure was 57.1 percent. (See chart 7.) In 1996, however, the Federal Government ended the Aid to

Families with Dependent Children program, replacing it with Temporary Assistance to Needy Families, a program that imposed work requirements on participants and rewarded States for moving welfare recipients, often single mothers, into the labor force. In New York City, the labor force participation rate began rebounding in 1996 and reached 59.9 percent in 2000. (The participation rate for women in New York City, which had been 47.1 percent in 1995, stood at 52.4 percent in 2000.)
In 1997, as chart 4 indicates, the pace of population growth in New York City picked up. The combination of a growing population and a rising participation rate resulted

## Chart 7. Labor force participation rates, United States, New York City, and balance of New York State, 1990-2008

Source: Bureau of Labor Statistics, Current Population Survey.
in large increases in the City's labor force. In 1996 the City's labor force expanded by 96,000 , and in 1997 it grew by an additional 139,000 . These were the two largest over-the-year increases in the 32 years for which the bls has published the current labor force series. One study of the effects of welfare reform found that the influx of single mothers accounted for 14 percent of the growth in New York City's labor force over the period from 1996 through 1999. 22 As the study noted, many of these women had low levels of educational attainment.
This labor force expansion was particularly opportune for the home health care industry. As noted earlier, in 1999 and later years New York City's elderly population was growing by at least 0.9 percent per year, increasing the demand for home health care services. Between 2001 and 2003, employment in the City's home health care industry jumped from 32,900 to 40,300 , an increase of 22.5 percent. The growth of this industry required hiring large numbers of nurses and home health aides, the latter being the dominant occupation in the industry. As table 4 illustrates, home health aides need only short-term on-the-job training. The City's labor force was in fact able to supply the required numbers of both health care professionals and aides who lacked significant educational and training credentials. In 2001, approximately 478,000
members of New York City's labor force older than 25 years ( 16.2 percent of the labor force over age 25 ) had less than a high school degree; the comparable national figure was 10.4 percent. ${ }^{23}$
The unprecedented expansion of New York City's labor force was accompanied by a rise in the unemployment rate from 8.2 percent in 1995 to 9.4 percent in 1997, as chart 8 illustrates. But after the recession in 2001 and the slow recovery, which stretched into 2003 and 2004, the City's unemployment rate drifted down and closer to the national average. In 2007, the City's rate reached 4.9 percent, its lowest annual average in the history of the unemployment rate series. In the balance of New York State, the unemployment rate was 5.0 percent or less from 2004 through 2007.
The low unemployment rates in the years 2004 through 2007 posed a challenge for human resource professionals in New York's health care industries. Unlike the situation in the late 1990s, health care spending was expanding at robust rates, particularly for the care of the elderly population. Unlike the situation in the early 1990s, the labor market was tight in both New York City and the balance of the State. A number of studies have called attention to the shortage of registered nurses and other health care occupations. For example, a survey of hospitals in New

Chart 8. Unemployment rates, United States, New York City, and balance of New York State, 1990-2008

York City, Long Island, and the Hudson Valley by the Center for Health Workforce Studies reported difficulties recruiting pharmacists, experienced registered nurses, nuclear medicine technologists, and physical therapists. ${ }^{24}$ One study of the City's nursing crisis also pointed out that nursing schools, like health care providers, were struggling to recruit and retain skilled nurses. ${ }^{25}$
The shortages of health care professionals reflect multiple factors, including constraints on the supply side of the labor market. ${ }^{26}$ The number of people aged $20-24$ years in the New York City labor force-the cohort that provides many entry-level workers-was almost unchanged over the 1995-2005 period. ${ }^{27}$ Educational requirements represent additional constraints. The number of people graduating as registered nurses in New York City declined from 7,685 in 1996 to 5,128 in 2002, before rising again. In 2006, the last year for which data are available, the number of registered-nurse graduations stood at 7,772, only slightly above the 1996 level. ${ }^{28}$ Indeed, in part because of the relatively slow growth of the domestic supply of nurses, the health care industry, both nationally and in New York City, has recruited nurses from overseas. ${ }^{29}$

Labor force diversity. Like other industries, health care industries in New York City operate in a labor market that, historically, has differed from national averages in
many respects. In 1990, for example, 26.1 percent and 20.0 percent of the City's labor force were Black and Hispanic, respectively. Nationally, the figures were lower: 10.9 percent and 8.5 percent, respectively.

Table 5 presents selected demographic characteristics of employees in health care industries. (Because of the small sizes of annual samples in New York City, the table uses 3-year averages.) Note that, in all three periods presented in the table, the vast majority of City residents who worked in health care were women. Not surprisingly, given that the labor force in New York City has higher-than-national concentrations of Blacks and Hispanics, so does the health care industry in the City. Reflecting New York City's traditional role as a port of entry, more than half of the health care workforce was foreign born during both the 2000-02 and 2006-08 periods.
Chart 9 illustrates the different patterns of immigration for workers in New York City. Roughly half of all employed residents of the City were native born during the 2006-08 period. Of the foreign born, 13 percent came from countries in the Caribbean, while 12 percent came from Asia, 11 percent from Central and South America, and 8 percent from Europe. In the health care industries, the native born accounted for 42.0 percent of workers. Thus, health care appears to be more reliant on foreignborn workers than are industries in general. In health care,

| Note: Persons whose ethnicity is identified as Hispanic or Latino can be of any race. Beginning in 2003, the methods for classifying race and industry changed, so data for the 2006-08 period are not strictly comparable to data for |  |  | earilier periods. Dash indicates datum not available. <br> Source: Current Population Survey. |  |  |  |

Chart 9. Distribution by geographic region of nativity of New York City residents empoyed in all industries and in health care industries, 2006-08 average

moreover, the share of workers from the Caribbean was almost one-fifth, with the share from Central and South America about 1 in 12. The distribution of registered nurses (not shown in the chart because of the small sample size) exhibited some similarities to that of health care workers in general, such as a high share from the Caribbean and a smaller share from Central and South America. This finding was consistent with that of another study which estimated that 3.8 percent of registered nurses in New York City were Hispanic. ${ }^{30}$

## Differences in employment growth rates

Table 1 shows that, over the period 1990-2008, health care employment in the Nation grew more strongly than in New York City (an average of 2.4 percent per year, compared with 1.8 percent), while the City's employment growth rate outpaced that of the balance of New York State (1.4 percent). Table 6 shows the average annual rates of growth and the shares of employment of detailed industries within health care. The table presents data for the
three-digit industries mentioned earlier (ambulatory care, hospitals, and nursing and residential care facilities), along with the four-digit industries within ambulatory care that are available for both the Nation and the City.
Nationally, employment in ambulatory care almost doubled over the 18 -year period examined; the average annual increase of 3.6 percent was the largest among the three-digit industries. Nursing and residential care facilities ranked second in employment growth among these industries, followed by private hospitals, while employment in State government hospitals contracted. Within ambulatory care, the four-digit industries shown in table 6 all had robust rates of job growth. Home health care services had the largest average annual growth rate ( 5.4 percent), followed by outpatient care centers ( 3.9 percent). Although these two industries experienced rapid rates of employment growth, their shares of health care employment were at or below 3.3 percent in 1990, and together they accounted for fewer than 1 out of every 5 jobs that the national health care industry added over the 1990-2008 period.
New York City had a similar pattern of growth across industries. At the three-digit level, ambulatory care had the strongest average annual growth rate ( 4.3 percent), and State government hospitals shed employment. (The rate of contraction in State government hospitals, 3.3 percent, was sharper than the 1.1 -percent national contraction rate.) Within ambulatory care, home health care services and outpatient care centers ranked first and second in employment growth (with rates of 7.1 percent and 3.5 percent, respectively), just as they did nationally.

New York City's health care industries had almost matched national job growth from 1990 to 1995 and then lagged behind. To understand this pattern better, it is useful to decompose the differences in employment growth by detailed industry. For any point in time, $t$, employment in the U.S. health care industry can be written as the sum of employment in seven of the eight detailed industries shown in table 6:

$$
\begin{equation*}
E_{t}^{\mathrm{US}}=\Sigma E_{t}{ }_{i}^{\mathrm{US}}=E_{t}^{\mathrm{US}}{ }_{1}+E_{t}^{\mathrm{US}}{ }_{2}+\ldots+E_{t}^{\mathrm{US}}{ }_{\gamma} \tag{1}
\end{equation*}
$$

The detailed industries are the four components of ambulatory care shown in the table, plus the other threedigit industries. The annual rate of growth of employment over the period of $T$ years is the number $g^{U S}$ such that

$$
\begin{equation*}
E_{T}^{\mathrm{US}}=E_{0}^{\mathrm{US}}\left(1+g^{\mathrm{US}}\right)^{T}, \tag{2}
\end{equation*}
$$

where $E_{0}{ }^{\mathrm{US}}$ is U.S. health care industry employment at the start of the period. Now, let $t=T$ in equation (1), divide by $\Sigma E_{0}{ }^{\mathrm{US}}{ }_{i}$, and rearrange terms. Then employment growth over the period of $T$ years can be expressed as a weighted sum of terms involving rates of employment growth in the detailed industries:

$$
\begin{align*}
& \left.\left(1+g^{\mathrm{US}}\right)^{T}=s_{0}{ }^{\mathrm{US}}\left(1+g_{1}^{\mathrm{US}}\right)_{1}\right)^{T}+s_{0}^{\mathrm{US}}\left(1+g_{2}{ }^{\mathrm{US}}\right)^{T}+\ldots+  \tag{3}\\
& s_{0}^{\mathrm{US}}\left(1+g_{7}^{\mathrm{US}}{ }_{7}\right)^{T},
\end{align*}
$$

where $s_{0}{ }_{i}$ is is industry $i$ 's share of health care employment

Table 6. Shares of industry employment and average annual rates of employment change in health care industries, United States and New York City, 1990-2008
(Percents)

| Industry (ownership) | NAICS | United States |  | New York City |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\begin{aligned} & \text { Share of } \\ & \text { employment, } \\ & 1990 \end{aligned}$ | Average annual rate of change, 1990-2008 | $\begin{aligned} & \text { Share of } \\ & \text { employment, } \\ & 1990 \end{aligned}$ | Average annual rate of change, 1990-2008 |
| Health care industries | None | 100.0 | 2.4 | 100.0 | 1.8 |
| Ambulatory health care services | 621 | 32.9 | 3.6 | 26.1 | 4.3 |

Source: Bureau of Labor Statistics, Current Employment Statistics Survey.
at $t=0$, the start of the period. Similarly, for New York City,

$$
\begin{align*}
& \left(1+g^{\mathrm{NYC}}\right)^{T}=s_{0}{ }^{\mathrm{NYC}}\left(1+g_{1}\left(1 \mathrm{NYC}_{1}\right)^{T}+s_{0} \mathrm{NYC}_{2}\left(1+g_{2}{ }_{2}\right)^{T}\right.  \tag{4}\\
& +\ldots+s_{0}{ }_{7}{ }_{7}\left(1+g^{\mathrm{NYC}}{ }_{7}\right)^{T} .
\end{align*}
$$

Subtracting the New York City equation from the national equation yields the following expression for the difference:

$$
\begin{align*}
& \left(1+g^{\mathrm{US}}\right)^{T}-\left(1+g^{\mathrm{NYC}}\right)^{T}=\Sigma_{S}^{\mathrm{US}}\left[\left(1+g_{i}^{\mathrm{US}}\right)^{T}-\left(1+g_{i}^{\mathrm{NYC}}\right)^{T}\right]  \tag{5}\\
& +\Sigma\left(s_{i}^{\mathrm{US}}-s^{\mathrm{NYC}}\right)\left(1+g_{i}^{\mathrm{NYC}}\right)^{T} .
\end{align*}
$$

A first-order approximation of the difference in annual growth rates, $g^{\mathrm{US}}-g^{\mathrm{NYC}}$, can be obtained by expanding the terms in $(1+g)^{T}$, subtracting the higher order powers of $g^{\mathrm{US}}$ and $g^{\mathrm{NYC}}$ from both sides, and dividing by $T$, the length of the period:

$$
\begin{align*}
& g^{\mathrm{US}}-g^{\mathrm{NYC}}=(1 / T)\left\{\Sigma \mathrm { S } _ { \mathrm { JS } } ^ { \mathrm { US } } \left[\left(1+g_{\mathrm{US}}^{\mathrm{US}}{ }_{i}^{T}-\left(1+g^{\mathrm{NYC}}\right)^{T}\right]+\right.\right.  \tag{6}\\
& \left.\left.\sum_{\left(s^{\mathrm{US}}\right.}^{i}-s^{\mathrm{NYC}}{ }_{i}\right)\left(1+g^{\mathrm{NYC}}{ }_{i}\right)^{T}\right\}+e .
\end{align*}
$$

In equation (6), $e$ is a residual term involving differences between the squares and higher order powers of $g^{\mathrm{US}}$ and $g^{\text {NYC }}{ }^{31}$ (To the extent that the growth rates are close to zero, the higher order terms are closer to zero and can be neglected.) On the right-hand side of equation (6), the term $\Sigma s^{\mathrm{US}}{ }_{i}\left[\left(1+g^{\mathrm{US}}{ }_{i}\right)^{T}-\left(1+g^{\mathrm{NYC}}{ }_{i}\right)^{T}\right]$ tells us how much of the difference in average growth rates is due to different growth rates within industries, with industry shares held constant, while the term $\Sigma\left(s_{i}^{\mathrm{US}}-s^{\mathrm{NYC}}\right)\left(1+g_{i}^{\mathrm{NYC}}{ }_{i}\right)^{T}$ tells us how much
of the difference is due to the different compositions of health care employment in the Nation and New York City. (These two terms are sometimes referred to as the "within effect" and the "share effect," respectively.)
Table 7 presents the differences in growth rates for the Nation and New York City and a decomposition of those differences for the entire 1990-2008 period and three subperiods. (For the entire period and each subperiod, the within effect and the share effect sum to within 0.1 percentage point of the actual difference, indicating that the residual term in equation (6) was generally close to 0.0.) As the table indicates, average growth rates for the 1990-95 period were relatively strong in both the Nation and New York City: 3.3 percent per year and 3.0 percent, respectively. During the 1995-2002 subperiod, when a number of measures previously discussed focused on reducing the growth of spending, particularly in hospitals, the rates of employment growth fell in the United States and New York City, but the deceleration was sharper in the City, and the difference between the average growth rates widened to 0.6 percentage point. In the last subperiod in the table, the pace of employment growth accelerated in both the Nation and the City, but the difference between the two did not narrow appreciably.
For the entire 1990-2008 period, differences in the growth rate of detailed industries accounted for all of the 0.6 -percentage-point difference in employment growth between the industry groups in the Nation and New York City. This finding is not entirely surprising, given that the Nation had stronger growth rates (or a smaller rate of loss) in 5 of the 7 industry components. The two detailed

NOTE: The average annual rates shown for the United States and New York City are based on published employment figures from the Current Employment Statistics survey. The percentage-point differences shown result from subtracting the percentage for New York from that for the United States, for each period. The decompositions in the last two columns were calculated by means of the
linear approximation discussed in the text. For each period shown, the sum of the last two columns might not equal the difference column because of nonlinearities and because growth rates were not constant within each period.

SOURCE: Bureau of Labor Statistics, Current Employment Statistics survey.
industries in which New York City had stronger growth were home health care and offices of physicians, and, as table 6 indicates, these industries had relatively small weights in equation (6). For the entire period, the share effect was relatively small ( 0.1 percentage point).
For the first subperiod, the within effect ( 0.5 percentage point) also dominated; the share effect was smaller and, again, negative ( -0.2 percentage point). As table 6 indicates, private hospitals were the detailed industry with the largest share of health care employment in 1990. This fact did not hurt the City's employment growth during the 1990-95 subperiod, because employment in the City's hospitals increased an average of 2.2 percent per year, double the national average of 1.1 percent.
For the years 1995 through 2002, the result of the decomposition was somewhat different. The within effect was 0.4 percentage point, reflecting the Nation's stronger rate of growth in private hospitals, which had the largest weight in equation (6), and in outpatient care centers and State government hospitals, which had much smaller weights. Unlike the first subperiod, the second subperiod saw a positive (0.3-percentagepoint) share effect that accounted for half of the total 0.6 -percentage-point difference. ${ }^{32}$ The positive share effect reflected the City's relatively higher share of employment in private hospitals. The positive share effect also reflected the City's lower share of employment in physicians' offices ( 9.6 percent in New York City, 14.8 percent in the Nation), as well as the strong growth rate in this industry (at or above 3.6 percent per year in both the City and the Nation).
The decomposition for the years 2002 through 2008 looks more like the decomposition for the first subperiod. Once again, the within-industry effect ( 0.9 percentage point) accounted for the total difference. The dominance of the within effect reflected the fact that the Nation had stronger growth in 6 of the 7 industry components. Private hospital employment in New York City increased by an average of 0.1 percent per year, while nationally the figure was 1.7 percent. One of the unusual aspects of the data for the detailed industries during these years was that State-governmentowned hospitals stopped losing jobs. At the national level, employment in this segment increased, while in the City it was relatively flat. The only detailed industry in which New York City had stronger growth was home health care. The share effect ( -0.3 percentage point) for this subperiod
reflected the City's larger-than-national share of employment in the home health care industry.

The YEARS 1990 THROUGH 1995, when New York City's health care industries came relatively close to matching the Nation's employment growth in those industries, were years when real spending on personal health care in New York, up an average 1.5 percent a year, grew more rapidly than national spending, up 0.9 percent per year. This larger-than-national increase in spending was accompanied by a larger-thannational increase in hospital employment in New York City, reflecting the City's traditional reliance on hospitals, rather than offices of physicians, to supply medical care.
The primary question explored in this article has been how to account for the wider difference in rates of employment growth in the years after 1995. A decomposition indicated that the difference was due both to stronger growth in detailed industries at the national level and to differences in industry composition. The growth-withinindustries effect reflected superior growth rates at the national level in private hospitals, the industry with the largest share of health care employment, and in outpatient care and State government hospitals. For the years in question, New York's City composition of health care employment, with its greater-than-national reliance on hospitals and less-than-national reliance on physicians' offices, also contributed to explaining the difference between the growth rates for the health care group.
For the years 2002 through 2008, the pace of growth in health care employment accelerated in both New York City and the Nation. For the City, the acceleration was due to the home health care industry (a component of ambulatory care), which increased employment at an average rate of 3.2 percent per year from 1995 through 2002 and at a rate of 9.7 percent per year from 2002 through 2008. Other industries within ambulatory care continued to expand payroll employment at average rates at or above 2.4 percent per year. But together, these industries added only 14,300 jobs over the period. Home health care was the real jobs machine in New York City for the years 2002 through 2008, adding more than 24,700 jobs. Its growth during those years reflected population growth, particularly among the elderly, and a labor market that could supply large numbers of workers with a variety of educational backgrounds.

## Notes

Acknowledgments: Ken Levasseur, supervisory economist in the Office of Employment and Unemployment Statistics of the Bureau of Labor Statistics,
and Mark Levitan, director of poverty research at New York's Center for Economic Opportunity, provided helpful suggestions and guidance on labor
force data. The New York State Department of Labor, Division of Research and Statistics, supplied the previously unpublished information on occupational employment and wages. The author assumes responsibility for any mistakes.
${ }^{1}$ The stronger-than-average rate of job growth in health care goes back through at least the 1980s. See David R. H. Hiles, "Health services: the real jobs machine," Monthly Labor Review, November 1992, pp. 3-16; and Jennifer M. Gardner and Howard V. Hayghe, "Slower economic growth affects the 1995 labor market," Monthly Labor Review, March 1996, pp. 3-16. Both of these articles used data based on the Standard Industrial Classification system, whereas the current series are based on the North American Industrial Classification System. Kimberly Riley, Emily Lloyd, and Natalie Propst, "Payroll employment and job openings rate continued to grow in 2006," Monthly Labor Review, March 2007, pp. 19-38, documented the fact that employment in private health care, in the current series, expanded more rapidly than total nonfarm employment over the period 2003-06.
${ }^{2}$ Other studies of New York City's health care industries have used different combinations of industries and ownerships. For example, Maria Kouznetsova, Robert Martiniano, and Jean Moore, The Health Care Workforce in New York, 2006: Trends in the Supply and Demand for Health Workers (Rensselaer, New York, Center for Health Workforce Studies, School of Public Health, State University of New York at Albany, January 2008), defined the health sector as including ambulatory care, hospitals, and nursing and personal care facilities for all ownerships, including Federal and local. Residential mental retardation, mental health, and substance abuse facilities (NAIcs 6232) were excluded.
${ }^{3}$ Examining how the growth of employment in the national, privately owned hospital industry varied over time, William C. Goodman, "Employment in hospitals: unconventional patterns over time," Monthly Labor Review, June 2006, pp. 3-14, found that, for the period 1990-2005, the rate of private hospital employment tended to be countercyclical.
${ }^{4}$ See, for example, R. Jason Faberman, "Job flows and labor dynamics in the U.S. rust belt," Monthly Labor Review, September 2002, pp. 3-10.

${ }^{25}$ Nurse retention and workforce diversity.
${ }^{26}$ In addition to the demographic and educational issues, significant numbers of nurses with degrees have chosen not to work as nurses. For a fuller discussion of why nurses chose to leave the profession, see Nurse retention and workforce diversity.
${ }^{27}$ This statement is based on unpublished data from the Current Population Survey.
${ }^{28}$ Kouznetsova, Martiniano, and Moore, The Health Care Workforce in New York, 2006.
${ }^{29}$ Nurse retention and workforce diversity.
${ }^{30}$ C. S. Brewer and T. Servoss, 2002 Registered nurses in New York State: county level nursing data, cited in Nurse retention and workforce diversity.
${ }^{31}$ Other decompositions are possible. For example, the difference can be decomposed by using the local area's weights to determine the within-industry growth effect and the Nation's changes in employment to calculate the share effect. Faberman, "Job flows and labor dynamics," used averages of the two areas as weights. If this alternative were pursued, one would expect the results to be an average of the first two alternatives.
${ }^{32}$ The use of New York City's weights to calculate the within-industry effect yielded different numbers, but substantially the same pattern. The absolute value of the share effects became smaller for each of the three subperiods. As with the results presented in table 7, the within-industry effect accounted for more than the whole difference in employment growth during the 1990-95 subperiod. By contrast, during the 1995-2002 subperiod the share effect was positive, namely, 0.2 percentage point, and accounted for approximately one-third of the difference in employment growth.

## APPENDIX: Sources and key concepts of labor market information

This article presents several different measures of employment and labor force status. Estimates of nonfarm payroll employment are from the Current Employment Statistics (CES, or establishment) survey. Estimates of occupational employment and wage rates for wage and salary workers in nonfarm establishments are from the Occupational Employment Statistics (OES) survey. Estimates of demographic characteristics and labor force participation in both New York City and the Nation are from the Current Population Survey (CPS, or household survey). The CPS is also the source of the data presented on the national unemployment rate, while the unemployment rates for New York City and the balance of New York State are from the Local Area Unemployment Statistics (LAUS) program of the Bureau of Labor Statistics (BLS). The CES, OES, and LAUS programs are Federal-State cooperative endeavors in which State employment security agencies use concepts, definitions, and technical procedures prescribed by the Bureau of Labor Statistics to prepare the data. The CPS is a sample survey of households that is conducted for the BLS by the U.S. Census Bureau.

## Nonfarm payroll employment

Employment data are from the CES survey and refer to persons on establishment payrolls who receive pay for any part of the pay period that includes the 12th of the month. Persons are counted at their place of work rather than at their place of residence.

## Occupational employment and wages

The OES survey defines employment as the number of workers who can be classified as full- or part-time employees, including workers on paid vacations or other types of paid leave; workers on unpaid short-term absences; salaried officers, executives, and staff members of incorporated firms; and employees for whom
the reporting unit is their permanent duty station, regardless of whether that unit prepares their paycheck. Straight-time gross pay, exclusive of premium pay, counts as wages in the OES survey. The worker's base rate; cost-of-living allowances; guaranteed pay; hazardous-duty pay; incentive pay, including commissions and production bonuses; tips; and on-call pay are included. Excluded are backpay, jury duty pay, overtime pay, severance pay, shift differentials, nonproduction bonuses, the employer's cost for supplementary benefits, and tuition reimbursements.

## Labor force and demographic data

The CPS and the LAUS program are the sources of the labor force and demographic data presented in the body of this article. The CPS measures employment and unemployment on a place-ofresidence basis. The universe for the Current Population Survey is the civilian noninstitutional population 16 years of age and older. Employed persons are those who did any work at all for pay or profit in the reference week (the week including the 12th of the month) or who worked 15 hours or more without pay in a family business or farm, plus those not working who had a job from which they were temporarily absent, whether or not paid, for such reasons as a labor-management dispute, illness, or vacation. Unemployed persons are those who were not employed during the reference week, who had actively looked for a job sometime in the 4 -week period ending with the reference week, and who were currently available for work; persons on layoff expecting recall need not be looking for work to be counted as unemployed. The labor force is the sum of employed and unemployed persons. The participation rate is the number in the labor force as a percentage of the population. The unemployment rate is the number of unemployed as a percentage of the labor force. The LAUS program uses the same concepts of labor force status, employment, and unemployment as the CPS.

# Employment growth in the Kansas City, MO-KS, Metropolitan Statistical Area 

From 1990 to 2007, there was a substantial narrowing of the gap between the higher level of employment on the Missouri side of the Kansas City Metropolitan Statistical Area and the lower level of employment on the Kansas side; leading the shift was robust growth in Johnson County combined with slow growth in Jackson County

Jacqueline Michael-Midkiff, Linda Nickisch, and Cassandra Yocum

Jacqueline Michael-Midkiff is a regional economist, and Linda Nickisch and Cassandra Yocum are economists, all in the Kansas City economic analysis and information office of the Bureau of Labor Statistics. E-mail: Midkiff.Jacqueline@bls.gov, Nickisch.Linda@bls.gov, and Yocum.Cassandra@bls.gov

The Kansas City, MO-KS, Metropolitan Statistical Area (MSA) is a bistate area currently consisting of nine counties in Missouri and six counties in Kansas. ${ }^{1}$ It is often assumed that Kansas City is in Kansas, yet the central business district of Kansas City is in Missouri and, historically, the Missouri side of the metropolitan area has had a far larger population than the Kansas side of the area. In fact, in 1990 (the year that the data used in this article begin) 61.2 percent of the population of the metropolitan area was on the Missouri side of the State line. By 2007, Kansas had increased its share of the Kansas City area population by 2.6 percentage points and Missouri's share had dropped to 58.6 percent. ${ }^{2}$

While there has been modest growth in the number of residents of the Kansas City area living on the Kansas side, there has been even more growth in the number working on the Kansas side. In fact, substantial employment growth on the Kansas side is closing the gap between the numbers of jobs on the two sides of the State line, with Kansas' share of the MSA's total employment increasing from 38 percent in 1990 to 44 percent in 2007. A
single county, Johnson, is responsible for more than 90 percent of the growth in the Kansas portion of the MSA.

This article uses data from the first quarter of each year from 1990 through 2007 to compare shifts in employment and identify the counties and industries that have been instrumental in leading growth in the Kansas portion of the metropolitan area to outpace growth on the Missouri side. All references in this article to the 1990-2007 period refer to data from the first quarter of each each year of the timespan. Monthly employment data from January, February, and March of each year were averaged to create the first-quarter estimates. For the purpose of industry analysis, the Bureau of Labor Statistics aggregates the largest industry sectors defined by the North American Industry Classification System. These aggregated groupings are called "supersectors," and there are 10 of them in private industry: natural resources and mining; construction; manufacturing; trade, transportation, and utilities; information; financial activities; professional and business services; education and health services; leisure and hospitality; and other services. For the purposes of this article, government is treated as an 11th supersector. However, detailed government data are avail-

## Levels of employment in the counties of the Kansas City, MO-KS, MSA, 2007

Source: Quarterly Census of Employment and Wages
able, categorized as Federal, State, or local with each of these categories divided into the same 10 private industry "supersectors" plus an additional "supersec-tor"-public administration. The employment and wage data examined in this article come from BLS' Quarterly Census of Employment and Wages (CCEW) program. ${ }^{3}$ This article focuses on "total covered employment," that is, all the employment documented in the QCEW; this includes both private and government employment. In this article, all references to increases or decreases in the number of jobs are references to the net number gained or lost, not to gross job gains or gross job losses.

## The Kansas City, MO-KS, MSA

The Kansas City MSA is centrally located in the Nation. Its geographical location and transportation infrastructure allow it to provide excellent support to the growth of the global market and are instrumental in attracting the mixture of industries that make up the area's economy. According to the Kansas City Area

Development Council, the Kansas City area is the secondlargest rail center in the country and ranks first in railroad freight volume. ${ }^{4}$ Other infrastructure includes three major interstate highways (one of which connects the southern border of the United States to the northern border), a designated Foreign Trade Zone, an international airport, barge lines that operate on the Missouri River, a motor freight hub, and the largest underground storage space in the Nation. ${ }^{5}$ Along with its high concentration of jobs in the trade, transportation, and utilities supersector, the Kansas City area also has a higher concentration of jobs than the national average in the information, the financial activities, and the professional and business services supersectors-typical of large metropolitan areas. ${ }^{6}$

Employment in the Kansas City MSA grew at a rate similar to that of U.S. employment from 1990 to 2007. Total covered employment grew 24.8 percent in the United States and 25.6 percent in the Kansas City area, with employment in the metropolitan area rising from 769,480 in the first quarter of 1990 to 966,555 in the first quarter of 2007. In addition, the Kansas City area's private-industry employment growth was on track with the Nation's, experiencing an increase of 26.4
percent compared with the Nation's 25.6 percent.
In the Kansas City MSA 4 of the 10 private-industry supersectors had rates of growth that were higher than the respective averages for the Nation-construction, natural resources and mining, information, and professional and business services. Two additional supersectors, financial activities and leisure and hospitality, grew at rates very similar to the national average. The largest supersector in the MSA-trade, transportation, and utilities-grew at a slower-than-average pace, along with the education and health services and the other services supersectors. Both nationally and locally, only the manufacturing supersector recorded a loss of employment over the 1990-2007 period; however, the Kansas City area lost manufacturing jobs at a slower pace than the Nation did.

Among the largest private-industry supersectors in the MSA are professional and business services, education and health services, leisure and hospitality, and construction. Each of these supersectors added more than 20,000 jobs to the metropolitan area and grew in excess of 40 percent over the 17 -year period.

## Comparing Missouri and Kansas employment

Although the Kansas City MSA and the United States as a whole had similar rates of employment growth from 1990 to 2007, growth was not evenly distributed between the portion of the metropolitan area in Missouri and the portion in Kansas. In fact, the Kansas portion added over twice as many jobs as the Missouri portion during the period. Total employment on the Kansas side of the State line grew 46.9 percent from the first quarter of 1990 to the first quarter of 2007 , compared with a 12.6 -percent increase on the Missouri side of the MSA. (See table 1.)

A look at employment shares illustrates the change that occurred from 1990 to 2007. Counties on the Missouri side of the metropolitan area made up 55.6 percent of the metropolitan area's employment in 2007, compared with 62.0 percent in 1990. (See chart 1.)

As metropolitan areas age, growth often moves from the central city to the suburban areas. This was certainly the case in the Kansas City area, with the long-time employment base, Jackson County, Missouri, registering similar levels of employment in both 1990 and 2007, whereas the more suburban Johnson County, Kansas, experienced an explosion of growth. The differing growth patterns in Jackson County, Missouri, and Johnson County, Kan-sas-the two largest counties in the area-led the shift in employment share between the Missouri and Kansas sides of the metropolitan area.

Jackson County, Missouri, is the largest county in the MSA-its estimated 2007 population is $666,000^{7}$ - yet in 2007 it barely registered any change from its 1990 level of 301,681 private-industry jobs. The second-largest county in the MSA, Johnson County-with an estimated 2007 population of 524,801 -is located on the Kansas side. Johnson County added more than 100,000 jobs to its private-industry payrolls for a total of 279,699 and experienced a growth rate of nearly 69 percent. In spite of the lack of growth in Jackson County, private-industry employment on the Missouri side of the metropolitan area grew over the 17 -year period because of a combined increase of more than 43,000 jobs in the smaller counties. In contrast, Johnson County provided the bulk of the growth on the entire Kansas side, as the five remaining Kansas counties in the MSA added a combined total of around 13,000 jobs over the period. Whereas the smaller counties on the Missouri side of the State line were the reason for growth in employment there, the smaller counties on the Kansas side had little impact.

Johnson County's total employment has experienced so much growth that in 2007 it accounted for 32 percent of the employment in the metropolitan area, up from 24 percent of the total in 1990. On the other hand, Jackson County accounted for 38 percent of the MSA total in 2007; in 1990 it accounted for 47 percent of employment in the area. In short, the difference in employment share between these two counties that drive employment in the MSA decreased from 23 percentage points to 6 percentage points over the 1990-2007 period.

## Factors that may effect employment growth

Wages. Like employment, the level and distribution of wages in the Kansas City MSA have shifted in favor of the Kansas side. In 1990, wages paid in the Missouri portion accounted for 62 percent of the total wages in the MSA. But by 2007, Missouri's share of total wages in the MSA had decreased to 54 percent. Interestingly, the nominal mean weekly wage (\$434) was the same on both sides of the State line in 1990. However, Kansas' nominal mean weekly wage increased more than Missouri's over the 17year period and was $\$ 860$ in 2007 compared with Missouri's $\$ 817$. This divergence in wage change suggests not only that Kansas added more jobs to the MSA than Missouri, but also that it shifted toward higher paying jobs.

The importance of Jackson and Johnson Counties to the MSA is reinforced further by an examination of county wages. (See table 2.) In addition to accounting for the majority of the jobs in the Kansas City area, Jackson and

Table 1. Employment growth in the United States; the Kansas City, MO-KS, MSA; and counties within the MSA; first quarter 1990 to first quarter 2007

${ }^{3}$ Data are a summation of figures from the individual counties of Bates, of Franklin, Johnson, Leavenworth, Linn, Miami, and Wyandotte Caldwell, Cass, Clay, Clinton, Jackson, Lafayette, Platte, and Ray in Missouri. Source: Quarterly Census of Employment and Wages.

Johnson Counties also account for most of the MSA's wages. Combined, these counties made up 70 percent of employment and accounted for about 75 percent of the wages paid in the MSA in 2007. They are the only counties in the entire MSA that accounted for a higher share of wages than of employment, which clearly indicates that both counties have jobs that are among the higher paying. While the nominal mean weekly wage in Jackson County rose from $\$ 449$ in 1990 to $\$ 873$ in 2007, the average wage grew at an even faster pace in Johnson County, increasing from $\$ 442$ to $\$ 910$ per week.

Educational attainment. ${ }^{8}$ The education level of the population is a factor that drives employment growth, and here a clear difference exists between the two largest counties. Eighty-four percent of the U.S. population age 25 and older has at least a high school degree and 27 percent holds a bachelor's or higher degree. Whereas the average level of educational attainment in Jackson County is similar to the average level of educational attainment in the Nation, the average level in Johnson County is clearly higher than the national average.

In Jackson County, approximately 87 percent of the
population is at least a graduate of high school and 26 percent has a bachelor's degree or higher. Much of the urban core of the MSA is located in Jackson County, and as Kansas City's population, jobs, and development continue to decentralize, the region's poor and minority residents remain concentrated in the core. ${ }^{9}$ The urban core of Jackson County contains a higher proportion of people with lower levels of education, whereas residents of some of the suburbs are more highly educated. The proportion of the population in Johnson County with a high school education or more is nearly 96 percent. Even more striking is that more than half ( 51 percent) of the population hold bachelor's or higher degrees. Johnson County has the greatest percentage of college graduates among the seven largest counties in the Kansas City MSA. ${ }^{10}$

A highly educated labor force is attractive to employers. Reverberations from growth associated with an educated labor pool include an increase in high-skill jobs and higher income levels, which typically generate more demand for goods and services among consumers. This higher demand leads to more consumer spending and even more job growth. Thus, greater educational attainment may provide a partial explanation for Johnson County's surge in employment.

Chart 1. Percent of total covered employment in the Kansas City, MO-KS, MSA held by Jackson County, Johnson County, and other counties, first quarter 1990 and first quarter 2007

Note: Values may not sum to total because of rounding.

Quality of life. Another likely reason that residents and businesses are drawn to the Kansas side is its reputation as a good place to live. Money magazine annually ranks the top 100 places to live, and two cities in the Kansas portion of the MSA made the 2006 list. Both are located in Johnson County and ranked in the top 15-with Overland Park placing 6th and Olathe 13th. The only city on the Missouri side to make the top 100, Lee's Summit (located in Jackson County), ranked 44th. ${ }^{11}$

## The MSA's two major employment bases

Jackson County, Missouri. Jackson County is the secondlargest county by population in the State of Missouri and is the location of Kansas City's central business district and much of the MSA's urban core. ${ }^{12}$ From 1990 to 2007, the population of Jackson County grew a modest 5.3 percent according to the U.S. Census Bureau, lagging well behind the national growth rate of 21.3 percent. Although Jackson County has historically been the largest county in the MSA and still has the highest employment level in the Kansas City area ( 364,529 total, with 301,695 in private industry), it contributed little to the growth of the area over the 17 -year period. Four private-industry supersectors and the government sector registered employment
growth of more than 5 percent, with growth in only two of these exceeding 20 percent. Nationally, nine private-industry supersectors and the government grew more than 5 percent, with all but four of these growing more than 20 percent. In all supersectors, Jackson County's employment growth was weaker than the employment growth of the Nation as a whole.

Johnson County, Kansas. Johnson County has the largest population of any county in the State of Kansas. During the period from 1990 to 2007, the population of Johnson County grew by 48.2 percent, more than double the national rate, and accounted for 92 percent of total population growth on the Kansas side of the MSA. Johnson County ranks second to Jackson County in total employment in the MSA, with total employment of 309,321 and private-industry employment of 279,699 , but has added the larger number of jobs in private industry $(114,031)$ and accounted for 90 percent of total private-industry employment growth on the Kansas side of the metropoli$\tan$ area. The rate of private-industry employment growth in Johnson County, 68.8 percent from the first quarter of 1990 to the first quarter of 2007, far outpaced the national growth rate of 25.6 percent. All but one of Johnson County's private-industry supersectors and the govern-

ment sector had rates of increase above 20 percent during the 17 -year timeframe used for this article, with four growing in excess of 100 percent. All of the supersectors and the government sector grew faster in the county than they did in the Nation as a whole; employment in six private-industry supersectors and in government grew more than twice as fast as in the United States as a whole.

Comparison. A comparison of employment growth among industry supersectors over the 17 -year period in Jackson and Johnson Counties shows Johnson County dominating in all but one supersector. (See table 3.) In five private-industry supersectors-construction, financial activities, professional and business services, education and health services, and leisure and hospitalityand in government, both Jackson County and Johnson County experienced job growth. However, except for in construction, where job gains were actually higher in Jackson than Johnson, the number of jobs added by each supersector in Johnson was more than twice as many as were added by each corresponding supersector in Jackson. And in every supersector in which employment in Jackson County declined over the period-natural resources and mining; manufacturing; trade, transportation, and utilities; information; and other servicesJohnson County added jobs.

## Employment in Jackson and Johnson Counties

Total employment. Johnson County, Kansas, consistently recorded stronger employment growth than Jackson County, Missouri, from 1990 to 2007. A look at more recent data shows that beginning in 2001 Jackson County recorded four consecutive over-the-year job losses, but turned around and gained jobs in 2005, 2006, and 2007. (See chart 2.) However, while Jackson County added a total of 6,122 jobs in 2005 and 2006, an increase of 1.7 percent, Johnson County added even more jobs, increasing employment by 11,126 , or 3.9 percent. From the first quarter of 2006 to the first quarter of 2007, Johnson County employment growth $(11,894)$ was more than seven times that of Jackson County $(1,669)$. A comparison of job growth among private-industry supersectors and government identifies the supersectors that had the largest impact on the overall difference in growth between the counties over the 17-year period. (See table 4.)

Trade, transportation, and utilities. The Kansas City MSA added 16,656 jobs in the trade, transportation, and utilities supersector from 1990 to 2007. This supersector-the largest one in both Jackson and Johnson Counties-presents a prime example of the shift in employment that has occurred over the past several years. Trade, transportation, and utilities grew 32 percent in Johnson County, adding

Source: Quarterly Census of Employment and Wages
the third-largest number of jobs $(15,924)$ to payrolls in the county from the first quarter of 1990 to the first quarter of 2007. Meanwhile, Jackson County lost 7,918 jobs (11 percent) in this supersector.

From 1990 through 2000, Johnson County's growth in
trade, transportation, and utilities was strong and nearly 19,500 jobs were added. During the same period, Jackson County recorded a total loss of around 3,500 jobs in the same supersector. Since then, the counties have performed similarly, both registering lower job totals in 2007 than

Chart 2. Annual net change in the number of jobs in the Kansas City, MO-KS, MSA's two largest counties, total covered employment, first quarter to first quarter, 2001-07

in 2000 but showing either growth or little movement in the most recent 3 years. Thus, although Jackson County had over 20,000 more jobs in this sector than did Johnson County in 1990, Johnson County had over 1,000 more jobs in the sector than Jackson County in 2007.

Within this supersector, retail trade employment in Jackson County lost out as employment in the suburban counties was expanding with the addition of new shopping areas and strip malls. Wholesale trade and utilities also recorded employment losses in the county while employment in transportation and warehousing was nearly stagnant. Johnson County was at the other end of the spectrum, with employment gains registered in wholesale trade, retail trade, and transportation and warehousing over the 17-year period.

Professional and business services. The Kansas City MSA added 59,943 jobs in the professional and business services supersector from 1990 to 2007. This supersector-the second largest in private industry in both Jackson and Johnson Counties-provided the largest number of new jobs in each of the MSA's largest two counties, but still reflects a divergence in growth. Professional and business services in Jackson County grew 30 percent, contributing 12,033 new jobs to the MSA, while Johnson County added 34,170 jobs in this supersector-an expansion of 133 percent.

In 1990, Jackson County had substantially more jobs in professional and business services than did Johnson County. However, the number of jobs in this supersector added in Johnson County from 1990 to 2007 was nearly three times the number added in Jackson County. Beginning in 2001, Johnson and Jackson Counties both experienced 3 years of job losses in this supersector, with Johnson County's 3 -year loss totaling 5,816 jobs and Jackson County's totaling 9,697 . In the 4 years since these counties began to again add employment in this supersector, Johnson added a total of 14,215 jobs while Jackson gained 4,590. As a result, Johnson County had over 8,000 more jobs in professional and business services than did Jackson County by the first quarter of 2007.

While most of the industry groups within this supersector added jobs in both counties, the number of new jobs was in most cases larger in Johnson County. A single industry group-employment services-added close to 10,000 jobs in Johnson County, but added a much lesser 1,153 jobs in Jackson County. The fast rate of employment growth in Johnson County in professional and business services, a supersector with a higher concentration of employment in the the Kansas City area than in the Nation as a whole, makes the supersector of increasing importance to Johnson County.

[^3]Information. The Kansas City MSA added 7,170 jobs in the information supersector over the 17 -year period. This industry provides yet another example of differences in employment changes between the two counties. While information employment fell 24 percent in Jackson County, a loss of 5,356 jobs, it surged 128 percent in Johnson County with the addition of 12,496 jobs. Further exemplifying the differences in growth between these counties, among all private-industry supersectors the industry group with the largest loss of jobs (a decrease of 5,244 jobs) in Jackson County was the same as the industry group that posted the largest gain $(11,328)$ of any industry group in Johnson County: wired telecommunications carriers. During the 1990-2007 period, a major telecommunications employer consolidated its multiple locations throughout the MSA into one major location in Johnson County, partially explaining the gain in information jobs in this county and the loss in Jackson County.

Interestingly, again among all industry groups within all supersectors, the industry group in which Jackson County outperformed Johnson County by the greatest number of jobs also was in the information supersector-data processing and related services. More than 2,500 more jobs in this industry group were added in Jackson County than in Johnson County over the period.

Recent data show that, following 5 consecutive years of job loss in Johnson County, employment in the information supersector rebounded and grew by more than 3,000 jobs from the first quarter of 2006 to the first quarter of 2007. Although the overall number of jobs in information is much smaller than in many other supersectors, information is frequently mentioned in regard to the economy of the Kansas City area because of the area's high concentration of jobs in this industry. The importance of the information sector to Johnson County has grown tremendously over the 17-year period, with the sector's concentration of employment in the county rising from almost twice the national average in 1990 to nearly triple the national average in 2007. By comparison, Jackson County experienced its seventh straight over-the-year job loss from the first quarter of 2006 to the first quarter of 2007. Despite the loss of jobs, the county also continued to have a substantially higher-than-average concentration of information-sector employment-about twice the national average in 2007.

Education and health services. The Kansas City MSA added 36,244 jobs from 1990 to 2007 in the education and health services supersector. Growth was seen in both counties, but at drastically different rates. In Johnson

County, the education and health services supersector added 19,412 jobs, an increase of 140 percent over the $17-$ year period. Jackson County employment in this supersector increased about 10 percent, adding 4,081 jobs-less than one-fourth of the number added in Johnson. During the 17-year period, Johnson County recorded no over-theyear job losses in this supersector; since 2001, the county has added more than 1,000 jobs in five of the seven years. Jackson County gained more than 1,000 jobs during only one year since 2001, and in one year (2004) lost in excess of 1,500 jobs. However, in 2007 Jackson County still had a higher employment level in education and health services, with 44,334 jobs compared with Johnson County's 33,284.

While both educational services and health care and social assistance contributed to Jackson County's increase in employment within this supersector, employment growth in health care and social assistance accounted for nearly all of the expansion in Johnson County. Among the industry groups that experienced the largest differences in growth between the counties were medical and diagnostic laboratories, physician's offices, and nursing care facilities, each adding well over 1,000 jobs to Johnson County's economy. Though growth in education and health services played a major role in job creation in Johnson County, in 2007 this supersector still had a below-average concentration of workers in the county as compared with the Nation as a whole, suggesting room for the supersector to grow in Johnson County simply to support the county economy.

Manufacturing. From 1990 to 2007, the Kansas City MSA lost 12,037 jobs in the manufacturing supersec-tor-the only supersector in which jobs were lost over the period. While employment in Johnson County increased 8 percent, an addition of 1,496 jobs, Jackson County recorded a 32 -percent decrease in employment (a loss of 12,720 jobs). Jackson County's job losses were widespread, with the industry group of other fabricated metal product manufacturing shedding 3,651 jobs, the most of any industry group within manufacturing. The county lost jobs every year from 1998 to 2007 with the exception of 2006 when the level of employment remained nearly unchanged. Conversely, Johnson County gained jobs in four of the five most recent years of the 17 -year period and in 2007 was one of three counties in the MSA to show an increase of more than 100 jobs in manufacturing employment.

Financial activities. The Kansas City MSA added 12,693 jobs in the financial activities supersector from 1990 to
2007. Whereas employment in the financial activities supersector increased only slightly over the 17-year timespan in Jackson County, it grew 60 percent in Johnson County and created 10,794 jobs. Within the supersector, the largest discrepancy in growth was seen in depository credit intermediation, which added 2,782 jobs in Johnson County but lost an even greater number in Jackson County. Insurance agencies, brokerages, and related businesses also experienced very different levels of growth in the two counties, with Johnson County adding more than 3,000 jobs and Jackson County adding around 1,000.

During the 1990s both counties shared in the growth of this supersector, with each county taking top honors in about half of the years. However, the degree of growth varied, and in total Johnson County added about twice the number of jobs as Jackson from 1990 to 2000. The last year that growth in Jackson fared better than growth in Johnson was 2000, and more recently the shift in growth has been even more pronounced, with Johnson County adding more than 3,500 jobs between 2004 and 2007 while Jackson County's employment remained nearly unchanged. As of 2007, both counties continue to have a much higher-than-average concentration of jobs in financial activities.

Leisure and hospitality. The Kansas City MSA added 27,194 jobs in the leisure and hospitality supersector from 1990 to 2007, an increase of 42.6 percent. Each of the two largest counties contributed to the supersector's increase in employment over the 17 -year period, with the addition of 3,718 jobs in Jackson and 11,138 in Johnson. The growth in both counties was primarily driven by the same industry group-full-service restaurants. This group added 7,295 jobs to payrolls in Johnson County and 4,233 in Jackson County. The rate of employment growth in full-service restaurants was 161 percent in Johnson and 52 percent in Jackson. Interestingly, employment growth in limited-service eating places was similar in the two counties, adding a little over 1,000 jobs to payrolls in each county. The amusement, gambling, and recreation industry subsector also was an area of strong growth for both counties, with the number of jobs in Johnson County increasing by 1,650 ( 106 percent) and in Jackson County rising by 966 (74 percent).

Johnson County added about three times the number of jobs in the leisure and hospitality supersector as Jackson County over the 17 -year period, and much of Johnson County's growth occurred in 2000 and earlier. After 2000, the over-the-year increase in employment in this supersector in the county surpassed 500 jobs only twice.

Growth in Jackson County has been equally dim since 2000, with no over-the-year increases in jobs exceeding 500 until 2007. In that year, Jackson County's addition of 930 jobs-an influx possibly related to the revitalization of the downtown area-was the largest either county had seen since 2000.

Government. The Kansas City MSA added 25,075 jobs in government from the first quarter of 1990 to the first quarter of 2007. Government payrolls increased in both counties over the period, with Johnson County $(11,267)$ adding more than twice as many jobs as Jackson $(4,647)$. The difference in growth is of particular interest considering the importance of government to Jackson County. Government accounts for 17 percent of the county's employment, second only to trade, transportation, and utilities. Comparatively, government ranks as the fourth-largest supersector in Johnson County and accounts for 10 percent of employment.

The largest government sector in both counties, local government (which includes public school systems), added 7,139 jobs in Jackson County, an increase of 23 percent. This sector's 82-percent growth in Johnson County-an increase of 11,634 jobs-strongly outpaced its growth in Jackson. Population growth and, more specifically, growth in the number of school-aged children, contributed to these changes in employment. While the number of children aged 5 to 17 grew 43 percent in Johnson County from 1990 to 2006, it increased only 7 percent in Jackson County. ${ }^{13}$ Employment in elementary and secondary schools grew 73 percent in Johnson County from the first quarter of 1990 to the first quarter of 2007 and accounted for more than 6,000 of the new jobs in local government. Jackson County added 2,798 jobs, commensurate with its smaller gain in school-aged children, and registered a job growth rate of 19 percent in elementary and secondary schools.

Employment in State government in Jackson County was up 24 percent, or 1,466 jobs, for the 17 -year period. Conversely, State government in Johnson County lost 190 employees, a decrease of 20 percent. The number of jobs in Federal Government declined in both counties, with Jackson County shedding 3,958 jobs, a reduction of 19 percent, and Johnson County down 6 percent, or 177 jobs, from its 1990 level.

Other services. The Kansas City MSA added 3,772 jobs in the "other services" supersector from the first quarter of 1990 to the first quarter of 2007 to reach a level of 26,704 jobs. Employment in other services, the second-smallest
supersector in the MSA, edged down in Jackson County over the period but grew by 2,620 in Johnson County, with about half of the growth occurring in personal care services-an industry group that recorded a small loss in Jackson County. Johnson County's highest levels of growth in the supersector occurred during the 1990s, and the county experienced job losses from 2004 to 2006. Both counties' employment levels were lower in 2007 than in the first quarter of 2004, but by less than 150 jobs.

Natural resources and mining. During the 17-year period, the Kansas City MSA added 372 jobs in the natural resources and mining supersector-the smallest supersector in the area. Even with its small number of jobs, the industry presents another example of the differing growth patterns in the two largest counties in the MSA. The number of jobs in natural resources and mining fell by 39 percent to a total of 216 jobs in Jackson County. Conversely, it grew 108 percent to a level of 451 jobs in Johnson County.

Construction. The Kansas City MSA added 21,835 jobs in the construction supersector from 1990 to 2007. Among all of the supersectors, only in construction did the two largest counties contribute similar numbers of new jobs to the MSA. Construction's potential to indicate future growth makes it all the more critical to this analysis. Construction employment in Johnson County increased 71 percent over the 17 -year period, an addition of 5,747 jobs. Surprisingly, the only county in the MSA to add more construction jobs over the period was Jackson County-a county that recorded little overall job growth. Construction exhibited the fastest rate of job growth of any supersector in Jackson County, increasing 46 percent with the addition of 6,005 jobs over the 17 -year span. In both counties, the industry group of building equipment contractors grew by more jobs than other industry groups in the construction supersector. Contributing the most to the differing levels of growth by number of jobs was nonresidential building construction, which added more than 1,300 jobs in Jackson County but fewer than 500 in Johnson County.

Job growth in construction slowed after 2000. In its largest over-the-year movement since then, Jackson County gained 2,076 construction jobs in 2006-possibly an early benefit of a concentrated effort to rejuvenate the central business district-but lost 846 in 2007 as revitalization projects wound down. From 2001 to 2007, Johnson County's employment in construction did not change from year to year by more than 700 jobs except for a loss of 1,255 jobs in 2002.

Summary of the supersectors' employment. Of the privateindustry supersectors and the government, six supersectors experienced growth in employment from 1990 to 2007 in Jackson County while five recorded losses of employment. Employment advances in professional and business services, construction, government, education and health services, leisure and hospitality, and financial activities were almost wiped out by declines in manufacturing; trade, transportation and utilities; information; other services; and natural resources and mining. In stark contrast, every private-industry supersector and the government in Johnson County added jobs. Eight of the 10 private-industry supersectors grew more than 50 percent over the period; four grew more than 100 percent. Government employment also grew more than 50 percent. In all but two of the supersectors, Johnson County contributed more new jobs than any other county in the entire metropolitan area.

In 1990, the majority of employment in all supersectors was in Jackson County. In fact, Jackson County had no less than 46 percent more jobs in every supersector than any other county in the MSA. Over the 17 -year period, employment in Johnson County grew to the extent that employment in the largest two supersectors - trade, transportation, and utilities, and professional and business ser-vices-and in the information and the natural resources and mining supersectors was higher in 2007 in Johnson County, Kansas, than in Jackson County, Missouri.

## Other counties in the Kansas City MSA

Although Jackson and Johnson Counties make up the majority of the workforce in the Kansas City area-no other county makes up more than 10 percent of the total employment of the MSA-several other counties experienced strong rates of growth from 1990 to 2007. If Johnson and Jackson Counties continue to perform as they did during this period, the performance of several of the smaller counties in the MSA may be key in determining whether the Missouri portion of the MSA can continue to maintain a larger share of total employment.

Three additional counties in the MSA have employment levels of more than 35,000-Clay County and Platte County in Missouri and Wyandotte County in Kansas. In addition to being among the larger of the "other counties," both of the Missouri counties experienced large employment gains over the period and became centers of growth that helped support the Missouri portion of the area when Jackson County did not.

Clay County, Missouri. Clay County is the second-larg-
est county on the Missouri side of the Kansas City MSA. It had a population of 211,525 in 2007 and is one of the fastest growing counties in the area. From 1990 to 2007 its population grew 38 percent. Total employment also is on the rise in the county, standing at 88,812 in 2007, an increase of 25,685 , or 41 percent, over its 1990 level. Clay County's jobs account for 9 percent of the MSA's total employment and 17 percent of total employment on the Missouri side of the State line.

Five private-industry supersectors in Clay County added more than 1,000 jobs over the period. The government and two private-industry supersectors-professional and business services, and leisure and hospitality-added more than 5,000 jobs and grew in employment by more than 75 percent. Employment in professional and business services grew by 6,029 , an increase of 121 percent and a figure equal to nearly one-quarter of the new jobs in Clay County. Government employment, which made up 16 percent of the county's total employment in 2007, increased by 6,025 jobs ( 77 percent) and accounted for about another one-quarter of the new jobs in the county. Nearly all of the increase in government employment can be attributed to education and health services, which includes jobs in public school systems. Leisure and hospitality added 5,442 jobs for an increase of 91 percent from the first quarter of 1990 to the first quarter of 2007.

Platte County, Missouri. Platte County, Missouri, ranks fourth in population among the Missouri counties in the Kansas City MSA, yet it ranks third in total private employment among the counties on the Missouri side. In 2007, Platte County's population grew to 84,881 , up 46.7 percent from its 1990 level, outpacing the Nation and all but one (Cass County) of the Missouri counties that make up the MSA. Total employment expanded by 14,180 jobs, an increase of 59 percent, over the 17 -year span. All 10 private-industry supersectors and the government added jobs over the period.

Two of the supersectors that drove growth in Clay Coun-ty-professional and business services, and leisure and hos-pitality-also led the expansion in the adjoining county of Platte. Professional and business services added 3,930 jobs over the 17 -year period, an increase of 122 percent. Employment in leisure and hospitality grew by 3,365 jobs, an increase of 125 percent. Two additional supersectors added more than 1,000 jobs and grew in excess of 50 percent: manufacturing employment increased by 1,633 jobs ( 119 percent) and employment in education and health services rose by 1,110 jobs ( 82 percent). Government employment growth also was strong, increasing by 1,303 (54 percent).

Wyandotte County, Kansas. The second-largest county on the Kansas side of the MSA and home to the city of Kansas City, Kansas, Wyandotte County made up 8 percent of total employment in the Kansas City MSA and accounted for 19 percent of the employment located on the Kansas side of the MSA in 2007. From 1990 to 2007, Wyandotte County was the only county in the Kansas City MSA to lose population, and the county contributed only slightly to employment growth on the Kansas side.

As of the first quarter of 2007, two supersectors recorded at least 1,000 more jobs than in 1990-education and health services, and leisure and hospitality. Education and health services added 5,153 jobs and accounted for the majority of private-sector employment growth in Wyandotte County over the 17-year period; virtually all of the new jobs were in health care and social assistance $(4,642)$, whose employment increased by 77 percent. Leisure and hospitality employment expanded by 1,516 jobs from the first quarter of 1990 to the first quarter of 2007. New jobs in accommodation and food services led the way in this supersector. Contributing to growth in accommodation and food services was the opening of Wyandotte County's Kansas Speedway in 2001. The Speedway hosts NASCAR and other racing events and has attracted hotels, restaurants, and other retail establishments to the area.

The largest supersector in Wyandotte County, trade transportation and utilities, did not record a higher level of employment in 2007 than in 1990. Government (with the second-largest employment level in the county) also decreased in size, as measured by employment. Trade, transportation, and utilities had little change in its employment level over the period, while government decreased its size by nearly 10 percent with a loss of 1,659 jobs.

Remaining Missouri counties. The remaining six counties that make up the rest of the Missouri portion of the Kansas City MSA-Cass, Lafayette, Ray, Clinton, Bates, and Caldwell-accounted for 4.7 percent of total employment in the Kansas City MSA in 2007. Cass County experienced a boom in population and job growth over the 1990-2007 period. Total employment in the county more than doubled, with 11,202 new jobs resulting in 102-percent employment growth and no supersector experiencing a decline. Trade, transportation, and utilities led the way with 3,534 new jobs created, followed by government, up 2,235 jobs, education and health services, up 1,445, and construction, up 1,308. Clinton County added 1,877 jobs over the period and Lafayette contributed 1,177 . Ray and

Bates Counties each added fewer than 1,000 jobs and Caldwell County was nearly unchanged.

Remaining Kansas counties. The remaining four counties that compose the rest of the Kansas portion of the Kansas City MSA-Franklin, Leavenworth, Miami, and Linn-accounted for 4.1 percent of total employment in the MSA in 2007. Franklin County exhibited the strongest growth among these counties, adding 3,119 jobs with close to two-thirds of the growth coming from trade, transportation, and utilities. Leavenworth and Miami Counties added 2,728 jobs and 2,336 jobs, respectively. Employment in Linn County was essentially unchanged from its 1990 level.

FROM 1990 TO 2007, KANSAS' SHARE of the Kansas City MSA's total employment increased from 38 percent to 44 percent, and employment on the Kansas side of the metropolitan area grew nearly four times faster than in the Missouri portion. Perhaps the most striking comparison is that the Missouri portion of the MSA had 63 percent more jobs than did the Kansas portion in 1990, but in 2007 Missouri's counties had only 25 percent more jobs than the counties on the Kansas side.

By a wide margin, the two largest counties in the area are Jackson County, Missouri, and Johnson County, Kansas. In 1990, Jackson County contributed substantially more jobs to the area than did Johnson County; by 2007, the gap was closing. The difference between the two counties' shares of the MSA's employment was 23 percentage points in 1990, but only 6 percentage points by 2007 .

Johnson County, Kansas, still ranks second to Jackson County, Missouri, in total employment in the MSA, but it added the largest number of jobs in the metropolitan area $(125,297)$ over the 17 -year period. Its surge in growth was spearheaded by the same industries that accounted for gains in employment in the MSA overall, and, from the first quarter of 1990 to the first quarter of 2007, every industry supersector grew at a faster pace than the national average. Employment in eight private-industry supersectors and
the government in Johnson County grew more than 50 percent over the period; employment in four of the supersectors grew more than 100 percent. Johnson County's employment advances in the two largest supersectors in the MSA-trade, transportation, and utilities, and professional and business services-led to 2007 employment levels that exceeded those of Jackson County. In 8 of the 10 private-industry supersectors, by number of jobs Johnson County contributed more net job growth than any other county in the MSA-further evidence that it was the growth of employment in Johnson County more than in any other county that supported the metropolitan area and also that Johnson County's employment growth was the reason that the Kansas side of the metropolitan area gained on the Missouri side.

With the most highly educated labor pool in the area and cities ranked among the most desirable in the country to live, Johnson County continues to have the potential for a high rate of employment growth. However, even if Johnson County continues to outpace Jackson County, it is still possible that the Missouri side as a whole can maintain its larger share of the MSA's employment. The ability to do this may depend on the Missouri side's second- and third-largest counties-Clay and Platte. These two counties each had over 35,000 jobs in 2007, while the Kansas side had only one county besides Johnson with employment above that level. This Kansas County, Wyandotte, showed lackluster growth in total employment over the 1990-2007 period. In contrast, employment increased by 41 percent in Clay county and by 59 percent in Platte County. Clay and Platte together added nearly 40,000 jobs over the period, helping to pick up the slack for Jackson County's lack of growth. Cass is another Missouri county that is worthy of mention. Although it had only around 22,000 total jobs in 2007, that is more than double the level of employment in 1990. If employment in Jackson County, Missouri, continues to perform as it has during the 1990-2007 timespan, it may be the employment growth in the smaller counties that allows Missouri to maintain its status as the primary State in the MSA.

## Notes

ACKNOWLEDGMENT:The authors thank Stan Suchman and Cheryl Abbot for their assistance in the preparation of this article.

[^4]Missouri) were added in 2003. For purposes of this study, data for all 15 counties were compiled to create statistics that are comparable from one period to another.
${ }^{2}$ Shares were calculated by summing county population data for each state and dividing by the population of the total metropolitan area. Calculations were made using 1990 and 2007 data located on a page of the U.S. Census Bureau Web site: http://factfinder.census.gov (visited Sept. 18, 2009). # Fifty years of BLS surveys on Federal employees' pay 

The process of adjusting compensation for General<br>Schedule (GS) Federal employees has changed considerably over the past 50 years; the change significantly affected the BLS occupational wage survey programs

John E. Buckley

John E. Buckley is a labor economist in the Division of Compensation Data Analysis and Planning, Office of Compensation and Working Conditions, Bureau of Labor Statistics. E-mail: buckley. john@bls.gov

In the winter of 1959-60, the Bureau of Labor Statistics (BLS) conducted its first survey specifically designed to compare salaries of white-collar workers in private industry with the salaries established in the 15 Federal General Schedule (GS) grade levels that covered a large majority of Federal white-collar workers. The National Survey of Professional, Administrative, Technical, and Clerical Pay (generally referred to as the PAT or PATC survey) was the result of a 1957 request "to design a survey that would provide information on salaries in private enterprises that could be compared with salaries in the Federal Civil Service." ${ }^{1}$ The request came from the Bureau of the Budget and the Civil Service Commission (now, respectively, the Office of Management and Budget and the Office of Personnel Management). Ultimately, the PAT became the model for future surveys designed for setting Federal GS pay levels.

Over the years, the Federal pay-setting process has been a topic of considerable debate, partly because of the large numbers involved-approximately 1.18 million GS employees received a 2009 pay increase, and the annual cost for the 1 percent of payroll that the President allocated for locality pay was estimated at $\$ 756$ mil-lion-and partly because of concerns over
survey procedures and pay-setting methodologies. A brief overview of the Federal workers' pay-setting process follows.

## A look back: 1883-1962

The path leading to the first PAT survey begins with the (Pendleton) Civil Service Act of $1883,{ }^{2}$ which failed in its goal to establish a merit system for Federal employment. Instead, individual departments controlled the pay process, and salaries and duties were not correlated. ${ }^{3}$ The Classification Act of $1923^{4}$ corrected the correlation omission by specifying that positions must be classified and graded according to duties and responsibilities; the Act also established a central classifying agency-the Personnel Classification Board—serving all departments.

The Classification Act of $1949^{5}$ superseded the 1923 Act in order to "bring position-classification closer to the needs of Government... and to clarify...and coordinate the distribution of authority between the (Civil Service) Commission and the various departments." ${ }^{6}$ The 1949 Act used work-level descriptions to extend a centralized job evaluation system to all white-collar positions, with the goal of ensuring that each job be compensated according to its relative place in a single hierarchy of positions. The Act also aimed at making a job evaluation system the centerpiece of Federal compensation. Merging several separate
"schedules" of pay rates into one "General Schedule,"7 the Act provided no timetable for adjusting GS pay rates, and changes were made sporadically by Congress. In the 13 years from 1949 to 1962, the average time between GS pay adjustments was about 31 months and ranged from 22 months to 44 months. The Federal Salary Reform Act of 1962 established procedures for conducting annual surveys of private industry for use in determining Federal pay adjustments. After the 1962 legislation was enacted, GS workers' pay was adjusted annually, except in 1963 and 1983, when no adjustment was made; in 1972, when there were two pay adjustments; and in 1986, when President Ronald Reagan issued an alternative plan that froze Federal pay until January 1987, when a 3 -percent increase became effective. The 1962 Act also shifted the focus on Federal GS compensation to pay reform, especially in regard to private industry and Federal pay comparability. The main focus of the 1883, 1923, and 1949 Acts was on classifying positions according to duties and responsibilities, along with applying the same standards across all Federal agencies.

## Federal Salary Reform Act of 1962

The Salary Reform Act of $1962^{8}$ specified the BLS as the agency authorized to conduct annual surveys of private industry to collect salary rates that could be used to set the salaries of Federal GS workers doing the same level of work and having comparable duties and responsibilities. Thanks to the 1957 request to conduct a white-collar survey and the 1960 completion of the first PAT survey, the BLS was well placed to respond to the 1962 congressional mandate. The survey covered professional, administrative, technical, and clerical occupations that were linked to the 15 GS occupational grades used by the Salary Survey Liaison Committee (composed of staff from the Civil Service Commission and the Bureau of the Budget) to make the private-Federal comparisons and prepare the required report for the President.

The occupational descriptions used in the survey were jointly developed by the Civil Service Commission (now the Office of Personnel Management, or OPM) and the BLS, with the Commission being responsible for ensuring that each level would incorporate the work characteristics necessary to determine a specific GS grade. The BLS was responsible for making sure that the descriptions were recognizable in a private-enterprise setting. The scope of the survey under the 1962 Act, in terms of industrial coverage and geography, was the responsibility of the Commission and the Bureau of the Budget, with the BLS providing advice.

The 1959-60 PAT survey was limited to selected private-
industry establishments in a sample of 60 Standard Metropolitan Statistical Areas (SMSAs) selected to represent the 188 SMSAs identified at that time. The scope of the survey excluded establishments in Alaska and Hawaii because of the Federal practice of paying added cost-of-living allowances to employees in those two States. (The Non-Foreign Area Retirement Equity Assurance Act of 2009 was introduced in Congress to extend the current locality pay program to those States. The legislation sometimes is cited as the Non-Foreign Area Retirement Equity Assurance (AREA) Act of 2009.) Also, coverage of the transportation industry was limited to local and suburban passenger railroads, deepsea waters, and air transportation, and the services industry was limited to engineering and architectural services and research, development, and testing laboratories. Establishments with fewer than 100 employees were excluded from the 1959-60 survey; for the 1961 through 1965 surveys, the minimum establishment size was 250 workers.

The scope of the survey also had to reflect Government pay policy, as determined by the Civil Service Commission and the Bureau of the Budget. At that time, pay policy called for national estimates, but no regional or local findings. From the beginning, the BLS role was to select a sample of establishments; collect, review, and tabulate salary data; and transmit published data to the appropriate authority (currently, OPM) for its use to compare Federal and private pay. ${ }^{9}$

After the 1962 comparisons were made and a report with recommendations sent to the President, the President sent the report to Congress recommending eventual full private-Federal comparability. The 1962 Act provided two new salary schedules. The first raised the annual salaries of all Classification Act (GS) employees an average of 5.6 percent, effective October 1962; the second, effective January 1964, raised salaries of GS grades 1 through 15 an average of 4.1 percent. Section 5332 of the Act, as amended, defined the GS as "a schedule of annual rates of basic pay, consisting of 15 grades, designated 'GS-1' through ‘GS-15."

Although the 1962 Act brought about improvements in the Federal pay-setting process, each pay adjustment still required an act of Congress, along with the usual accompanying political debate and delays. The passage of the Federal Pay Comparability Act of $1970^{10}$ established procedures for adjusting GS pay by executive action, eliminating the yearly need for special legislation.

## Federal Pay Comparability Act of 1970

As with earlier Federal pay legislation, the Federal Pay Comparability Act of 1970 provided for an agent-known
as the President's Pay Agent-that had the responsibility for interpreting the comparability law and providing the President with recommendations on pay adjustments. Initially, the Agent comprised the directors of what are now the Office of Personnel Management and the Office of Management and Budget. A 1977 Presidential Executive order added the Secretary of Labor, forming a three-party Agent.

Under the 1970 Act, the Agent was empowered to create a five-member Federal Employees Pay Council and was required to meet with the Council, whose membership consisted of union officials. The Agent must "give thorough consideration to the views and recommendations of the Council" in three essential areas:

- The coverage of annual surveys conducted by the BLS,
- The process used to compare Federal and private pay for the same work levels, and
- The pay adjustment required to achieve comparability.

The 1970 Act also specified that the Council's views on Federal pay adjustments be included in the Agent's report to the President. Ultimately, the final recommendation on these pay issues rested with the Agent. In addition to creating the Council, the Act established the Advisory Committee on Federal Pay, consisting of three private-sector pay experts. After reviewing the Agent's and the Council's recommendations, the Committee made its own recommendations to the President and included any other information that it believed appropriate.

## Definitions

The 1962 and 1970 Acts included references to paying Federal GS workers salaries comparable to the salaries of private-industry employees doing the same level of work. The Federal Employees Pay Comparability Act of 1990 (FEPCA), discussed later, has a similar reference, but expanded the comparison to non-Federal employees, thereby including State and local governments. The President's Pay Agent had the task of interpreting "comparable" salaries of employees doing the "same level of work." Regarding the comparability requirement, George Stelluto noted that

Private enterprise pay rates, even within narrowly defined work levels, vary substantially among the many types of establishments in which the work is performed. Entry-level professional engineers (recent college graduates), for example, had private-sec-
tor salaries ranging from about $\$ 975$ to more than \$1,600 a month in March 1977-a salary spread of more than 65 percent. ${ }^{11}$

Stelluto followed up with a question:
How then does the Federal Government make its salaries "comparable" to the widely dispersed rates paid by private enterprise?

The Agent determined that under the 1962 Act "private industry" would denote all classes of private-enterprise establishments with sufficient numbers of workers in the occupations surveyed to influence the survey estimates materially. Because it was thought that establishments with few employees typically would pay lower wages than larger establishments, using the rates of small establishments for Federal pay comparison purposes became an issue. The 1959-60 PAT survey excluded establishments with fewer than 100 employees. From 1961 through 1965, establishments with fewer than 250 employees were excluded from the survey. In 1966, the minimum size was lowered in some industries and ranged from 50 employees in finance, insurance, and real estate to 250 in manufacturing and retail trade.

To address the requirement of the 1962 and 1970 Acts to develop data that would reflect the "same level of work" in comparisons of Federal and private-industry pay, the PAT surveys produced data by level for occupations designated by the Agent. In the March 1977 survey, for example, 19 white-collar occupations comprising 81 work levels were studied. Work levels are an established hierarchy of the difficulties and scope of the primary duties and responsibilities of individual jobs related to either a grade or salary level. The PAT survey levels ranged from one, for messengers, to eight, for professional engineers and chemists. The occupations studied produced data for the 15 GS Federal grades, except GS-10. The list of occupations and descriptions used for Federal pay-setting purposes was kept up to date from the passage of the 1962 legislation through the mid-1990s. The boxes on pages 39 and 40 respectively provide a brief explanation of the current process that is followed in obtaining occupational levels and an example of definitions of grades GS-7 and GS-12 of a multilevel occupation.

The National Compensation Survey (NCS) uses a "generic leveling" technique to match occupations by level. Initially, a 10 -factor leveling system was used to determine the level of selected occupations; the 10 -factor system is being phased out by the 4 -factor system shown in the box on page 39. A major difference between the two systems is that the 4 -factor sys-

## Determining work levels

During the final step before data on wage rates and hours worked are collected, each sampled job is evaluated to determine the work level of its duties and responsibilities. This process is known as point factor leveling, because it categorizes certain aspects of a job into specific levels of work with assigned point values. Points for each factor are then totaled to determine the overall work level for the job.

In point factor leveling, an occupation is matched to a level within each of four factors:

- Knowledge
- Job controls and complexity
- Contacts (nature and purpose)
- Physical environment

Each factor consists of several levels, with associated descriptions and assigned points. The description within each factor best matching the job is chosen. Points for the four factors are recorded and totaled. The point total determines the overall work level of the occupation. The knowledge and job controls and complexity factors are given more weight than the contacts and physical environment factors.

A full discussion of the leveling process appears on the Internet at http://www.bls.gov/ncs/ocs/sp/ ncbr0004.pdf (visited Sept. 8, 2009).
tem slots each selected occupation into 1 of 24 knowledge guides. In an article on the use of the NCS in predicting wage rates, Brooks Pierce noted that

These [generic] data elements are "generic" in the sense that they do not rely on identifying the occupation in question. This facilitates the collection of these data for random samples of jobs that cover the broad range of occupations in the economy. It also gives some basis for comparing or classifying occupations that are distinct but that may have similar duties and responsibilities. ${ }^{12}$

Differences in definition for each level of a multilevel job reflect the complexity of the job. In the box on page 40, the GS-7 accountant performs "under general supervision, work of considerable difficulty and responsibility," while the GS-12 accountant performs, "under general administrative supervision, [work] with wide latitude for the exercise of independent judgment." Further, the GS-7 does "work of considerable difficulty and responsibility," whereas the GS-12 does "work of a very high order of difficulty and responsibility." And so on.

## Developing issues

In the middle and late 1980s, Federal agencies had considerable difficulty recruiting and retaining high-caliber
employees to carry out the Government's increasingly complex mission. To ease the problem, the Office of Personnel Management extended the application of special pay rates to certain groups of workers in selected localities. In spite of these efforts, the Federal Government's recruitment and retention problems persisted. In hearings before a congressional subcommittee, Constance B. Newman, former Director of the Office of Personnel Management, stated, "Every agency in the Government is having some type of problem with the pay system. Continued fragmentation of the Government-wide pay system will only frustrate and delay the needed solution...we must have a pay system that is more flexible and responsive to the labor market." ${ }^{13}$ Congress and the White House agreed that sweeping changes were needed; FEPCA was the vehicle used to make those changes.

## FEPCA (1990)

In November 1990, President George H. W. Bush signed into law the Federal Employees Pay Comparability Act (FEPCA) of 1990, ${ }^{14}$ marking a major milestone in legislation related to the compensation of Federal white-collar workers. Current Federal pay adjustments are made under this Act, three features of which stand out:

- The creation of a locality-based pay system to replace the single general schedule that largely disregarded locality pay differences found in the private sector,

## Determining work levels: an example

The 15 GS grade levels are codified under section 5104 of Title 5. Following are definitions for two levels of a multilevel occupation (for example, accountants) and how the duties and responsibilities of those levels differ:
(7) Grade GS-7 includes those classes of positions the duties of which are-
(A) to perform, under general supervision, work of considerable difficulty and responsibility along special technical or supervisory lines in office, business, or fiscal administration, or comparable subordinate technical work in a professional, scientific, or technical field, requiring in either case-
(i) considerable specialized or supervisory training and experience;
(ii) comprehensive working knowledge of a special and complex subject matter; procedure, or practice, or of the principles of the profession, art, or science involved; and
(iii) to a considerable extent the exercise of independent judgment;
(B) under immediate or general supervision, to perform somewhat difficult work requiring-
(i) professional, scientific, or technical training; and
(ii) to a limited extent, the exercise of independent technical judgment; or
(C) to perform other work of equal importance, difficulty, and responsibility, and requiring comparable qualifications.
(12) Grade GS-12 includes those classes of positions the duties of which are-
(A) to perform, under general administrative supervision, with wide latitude for the exercise of independent judgment, work of a very high order of difficulty and responsibility along special technical, supervisory, or administrative lines in office, business, or fiscal administration, requiring-
(i) extended specialized, supervisory, or administrative training and experience which has demonstrated leadership and attainments of a high order in specialized or administrative work; and
(ii) intimate grasp of a specialized and complex subject matter or of the profession, art, or science involved;
(B) under general administrative supervision, and with wide latitude for the exercise of independent judgment, to perform professional, scientific, or technical work of marked difficulty and responsibility requiring extended professional, scientific, or technical training and experience which has demonstrated leadership and attainments of a high order in professional, scientific, or technical research, practice, or administration; or
(C) to perform other work of equal importance, difficulty, and responsibility, and requiring comparable qualifications.
(From "U.S. Code Collection, §5104. Basis for grading positions" (Ithaca, NY, Cornell University Law School, no date), on the Internet at www.law.cornell. edu/uscode/search/display.html?terms=grade\&url=/ uscode/html/uscode05/usc_sec_05_00005104----000-.html (visited Sept. 8, 2009).)

- A timetable for reducing gaps that may exist between the pay of Federal and non-Federal employees doing comparable work in the same locality, and
- Specifying "non-Federal" workers rather than "pri-
vate industry" for pay comparability purposes. This feature essentially adds State and local government workers to private-industry workers as the industry scope against which Federal Government workers are to be compared in respect of pay.

Once again, the legislation named the BLS as the agency in charge of conducting surveys for use in determining locality pay levels. To accommodate the requirements of the Act, the traditional occupational pay surveys of the BLS were changed considerably, with resources formerly dedicated to three specific survey programs (the PAT, Area Wage Survey, and Industry Wage Survey) now being used to carry out an improved and expanded locality pay program. The new program, which evolved over the years into the NCS, permitted the presentation of occupational and industrial detail that was either unavailable in the past or available only at the national level. The NCS provided the following improvements, on a locality basis, to the numerous private- and public-sector users of BLS data:

- Improvement in coverage of State and local government establishments,
- Expansion of private-industry coverage to all nonagricultural establishments (except private households) with 50 or more employees (now 1 or more),
- Expansion of professional and technical jobs,
- Expansion, in the mid-1990s, to cover all jobs, using a probability-selection-of-occupations technique, rather than the collection of a limited number of jobs on a predetermined list,
- Publication of measures of sampling error and response rates, and
- Improvement of the analytic potential of the statistical database.

The Act retained the three-party President's Pay Agent function, making it responsible for interpreting FEPCA, selecting and defining the pay localities, determining the occupational and industrial scope of the area surveys, designating the minimum size of the establishments to be surveyed, establishing appropriate pay lines based on BLS data, and preparing and submitting annual reports to the President.

A Federal Salary Council, consisting of nine members appointed by the President, also was established by FEPCA to provide views and recommendations on a variety of related topics to the Pay Agent, including the establishment or modification of pay localities, the coverage of annual surveys conducted by the BLS, the process of comparing Federal and non-Federal pay, and the level of comparability payments needed to eliminate or reduce pay disparities. Three of the Council members are chosen on the basis of their impartiality and knowledge in the field of labor rela-
tions and pay policy, and the remaining six members are from employee organizations that represent substantial numbers of Federal GS workers.

Under FEPCA, the Pay Agent is required to "give thorough consideration to the views and recommendations of the [Federal Salary] Council and...individual...members...." The Pay Agent also is required to "give thorough consideration to the views and recommendations of employee organizations not represented on the Council...." The Pay Agent's report to the President must include the views or recommendations of these groups or individuals.

## FEPCA: plan and performance

The 1990 legislation established a plan for annual adjustments to Federal employees' pay through the early part of the 21st century. Beginning January 1994, annual salary adjustments for most GS employees would consist of two parts. The first part would equal the national percent increase for wage and salary workers in private industry as indicated by the BLS Employment Cost Index (ECI), minus one-half percentage point. (The ECI is a quarterly measure of change in total compensation costs for civilian workers, with separate estimates for the cost of wages and salaries and the cost of benefits.) $)^{15}$ The second part, based on BLS special area occupational pay surveys, may not "be less than one-fifth of the amount needed to reduce the pay disparity of the locality involved to 5 percent." ${ }^{16}$

The second of these two increases would close the pay gap (to within 5 percent) by making additional adjustments from 1995 through 2002. That is, a three-tenths adjustment to the pay gap was to be made in 1995, twofifths in 1996, and so on, until the gap would be no greater than 5 percent in 2002. Workers in localities that are already within the 5 -percent band would get the national ECI increase (minus one-half percentage point), but not the locality adjustment.

Under FEPCA, the President has the authority to fix an alternative level of comparability payments in situations where there is a "national emergency or serious economic conditions affecting the general welfare." The first pay adjustment under FEPCA was effective in January 1994. Alternative plans were submitted for pay increases effective in 1995-98, 2001, 2003-05, 2007, and 2008; no alternative plans were submitted for pay increases effective in 1994, 1999, 2000, 2002, 2006, or 2009.

From 1994 to 2009, Congress either added to the President's proposed adjustment or equaled the higher rate recommended for the military. The pay gap was scheduled to be eliminated (to within 5 percent) in 2002. Table 1

| NOTE: Dash indicates that the area was not used for locality pay purposes in 1993 or that there was no survey that year. <br> SOURCE: Table 4 of the 2008 Pay Agent's Report to the President on Lo- <br> cality Pay for 2010 and enclosure in the Appendices to the Annual Report of the President's Pay Agent, 1993. |  |  |  |

shows the estimated pay disparity in 1993 and 2008; it also indicates that, in terms of performance, the disparity was not reduced as planned.

The pay disparity narrowed for 17 of the 21 areas for which comparisons could made, most notably the 22.70-percentage-point shrinkage in Houston (from 39.22 percent to 16.52 percent) and the 14.28 -percentage-point shrinkage in Cincinnati (from 27.18 percent to 12.90 percent.) The disparity for Washington, DC, widened by 9.62 percentage points over the period, from 27.23 percent to 36.85 percent. The disparity widened slightly in Atlanta, from 25.29 percent in 1993 to 26.35 percent in 2008. The gap also widened slightly for San Diego and Seattle. The
wide gap in pay disparity among localities reflects, in part, both the pay levels in the areas when the first comparisons were estimated and subsequent changes in local economies and survey methods.

## Issues

Before the first FEPCA pay adjustments were effective, two issues emerged that proved to be persistent: occupational coverage and the appropriateness of the methodology used to set Federal white-collar workers' salaries. Under its PAT survey, the BLS collected data for a predetermined list of occupations that was developed jointly
with OPM. As noted earlier, published survey results were sent to OPM for setting Federal GS pay. This arrangement continued during the 1991-96 period, when the program was designated the Occupational Compensation Survey (OCS). Because of budgetary constraints and the issue of respondent burden, the BLS once again was compelled to merge three surveys: the occupational wage (locality) survey, the ECI survey, and the Employee Benefits Survey. At that time, the new NCS dropped the use of a predetermined occupational list, the method preferred by the Pay Agent. In its place, to select occupations, the BLS employed the probability-selection-of-occupations technique mentioned earlier.

In addition to dealing with the issue of occupational coverage, the Agent had other concerns that were spelled out in a five-point action plan in 1999. The first four points, already incorporated into the NCS, produced the following improvements:

1. A linkage between Federal and non-Federal jobs, accomplished by developing a crosswalk between General Schedule occupations and the Standard Occupational Classification (SOC) system to permit weighting data by Federal employment.
2. The development of methods to identify and exclude survey jobs that would be graded above GS-15 in the Federal Government.
3. The development of an econometric model based on survey data to estimate salaries for jobs not found in the probability samples.
4. The development and implementation of better methods for grading supervisory jobs selected by probability sampling. ${ }^{17}$

The last point, which will be completed in surveys delivered to the Pay Agent in 2011, involves a four-factor job-grading system with families of jobs to be used as guides to improve grade leveling under the NCS. The BLS continues to phase in this improvement. In the meantime, updated OCS data were used by OPM for several years while the improvements were being implemented. All of the improvements are described in the 2002 Pay Agent's report to the President. ${ }^{18}$

In its 2007 report, the Pay Agent included the following paragraph:

The new survey process was not immediately accepted for use in the locality pay program. In fact, the Federal Salary Council recommended that the
original NCS methods not be used to set Federal pay. After reviewing test data and several years of production surveys, the Pay Agent agreed with the Federal Salary Council's conclusion that the NCS program, as originally configured, should not be used for the locality pay program. However, the Pay Agent did not ask BLS to reinstate the previous methodology. The Pay Agent concluded that the NCS program has several advantages over the previous salary survey program, the Occupational Compensation Survey (OCS) program. These include offering greater occupational coverage, being less costly, and being less burdensome on respondents. ${ }^{19}$

The other outstanding issue, the method for determining the pay-setting process, was the subject of the aforementioned April 2002 White Paper ${ }^{20}$ published by OPM, which identified three factors that contribute to the "credibility gap" in setting Federal pay. Shortcomings were found in FEPCA's

- definition of comparability,
- methodology and precision, and
- summary statistic

Comparability. The White Paper contends that (1) FEPCA's definition of comparability is reflected in its statutory principle that "Federal pay rates be comparable with non-Federal pay rates for the same levels of work within the same local pay area" and (2) its two-dimensional con-cept-grade and locality-"bears little resemblance to the reality of labor markets." The document goes on to explain that "labor market shortages and excesses are described and analyzed in terms of occupations, skills, specialties, and locations, not grade level." ${ }^{21}$

A section titled "Labor Markets Are Not Supermarkets" contends that grade, being the major determinant of base pay, presumes that workers in the same GS grade are equal. For example, the Federal Government will pay GS-12 budget analysts, GS-12 attorneys, and GS-12 human resource specialists the same amount of money, unless agencies document the need to do otherwise. The narrative goes on to say, "Most employers do not make this presumption, because they recognize that employees in different occupations are not interchangeable. For example, a GS-13 attorney is not a satisfactory substitute for a GS-13 biologist." ${ }^{22}$

Methodology. The second factor underlying FEPCA's credibility gap, according to the White Paper, is that its
methodology presumes an unrealistic level of precision and requires lengthy deliberation, both at the expense of relevance and strategic utility. Under FEPCA, general pay increases are based on changes in the Employment Cost Index (ECI). Locality payments, which are calculated to one one-hundredth of one percent, are based on surveys of salaries in each locality pay area. Because these surveys are extensive and statistically rigorous, significant time lags occur between data gathering and pay-setting and implementation. After adding the time that the Federal budget planning and appropriation processes must necessarily entail, the result is a tenuous relationship between pay adjustments and current market conditions. ${ }^{23}$

Summary statistic. The third factor diminishing FEPCA's credibility is that
its statutory language requires the calculation of a single average pay gap in each locality pay area. Even though sophisticated methods of weighting are used to take into account the actual presence and distribution of Federal work, the result nonetheless disguises and ignores substantial differences in the degree to which

Federal and non-Federal salaries for particular occupations or grades differ. By its very nature an average [median] is describing a set of values half of which are higher and half are lower than the summary statistic. In this instance, the average the law requires us to use in describing a "pay gap" is no Golden Mean, but more of a Great Muddle that describes nothing very meaningfully and masks the relevant differences across occupational levels of work in each locality pay area, to the strategic detriment of the entire approach. ${ }^{24}$

On December 2, 2008, the Pay Agent sent its latest annual report to the President. It included the following paragraph, which had a theme similar to that in other annual reports going back to at least 2003:

We continue to believe in the need for fundamental reforms of the white-collar Federal pay system. As we have previously reported, the Pay Agent has serious concerns about the utility of a process that requires a single percentage adjustment in the pay of all whitecollar civilian Federal employees in each locality pay area without regard to the differing labor markets for major occupational groups or the performance of in-

dividual employees. In addition, we continue to have major methodological concerns about the underlying model for estimating pay gaps. ${ }^{25}$

Although the Federal white-collar pay issue has been discussed for several decades, it shows no sign of being resolved to everyone's satisfaction. The estimated 2008 Federal GS payroll of $\$ 75.8$ billion provides sufficient reason to examine the pay-setting process closely to ensure that the Federal worker is equitably compensated and that the American taxpayer receives full value for the amounts expended. Table 2 shows year-to-year percent increases in Federal GS employee pay from 1965 to 2009.

Besides the Federal GS pay system, there are numerous other Federal pay systems, some of which are established
by individual laws and some by administrative determination. The box on this page presents some examples of major Federal pay systems established by law.

The bureau of labor statistics continues to work with the Office of Personnel Management and others in the Federal pay community to carry out its commitment to produce accurate and timely data for policymakers and other users. The wage and salary information that the BLS collects is part of its broader measures of compensation that includes detailed information on employee nonwage benefits. The past 50 years have seen constant changes and improvements in BLS programs. If the past is any guide, the next 50 years will be just as challenging and rewarding, and, as in the past, the BLS will be ready for the task.

## Examples of pay systems established by law

Foreign Service pay plans and salary schedules for Officers (pay plan FO) and Personnel (FP) were established under the Foreign Service Act of 1980. Other Foreign Service pay plans linked to Federal pay schedules are Chiefs of Mission (FA), linked to the Executive Schedule, and Senior Foreign Service (FE), linked to the Senior Executive Service. (See shortly.) Under title 38, the Veterans Health Administration in the Department of Veterans Affairs provides unique pay plans for their physicians and dentists (VM), podiatrists and optometrists (VP), and nurses (VN).

The Executive Schedule (in 5 U.S.C.5311-5318) was established by Congress to cover top officials in the executive branch. As mandated in subchapter II of chapter 53 of Title 5, United States Code, this schedule has five levels, each with a single rate. In 1989, the Ethics Reform Act linked Executive Schedule increases to increases in the Employment Cost Index (ECI).

The Senior Executive Service (SES) (in 5 U.S.C. 5382) covers most managerial, supervisory, and policy positions
in the executive branch that are classified above GS-15 and do not require Senate confirmation. SES pay is set by the President at the same time as the annual increases are authorized for the GS.
The National Security Personnel System (NSPS) (in 5 U.S.C. Chapter 99) is a U.S. Department of Defense system designed to create a civilian workforce that is focused on competency and based on performance, putting the right people in the right jobs at the right time. The NSPS accelerates the Department's efforts to create a Total Force (military, civilian, Reserve, National Guard, and contractors) that operates as one cohesive unit, with each individual performing work most suited to his or her personal skill set. The key components of the NSPS are a classification system, a compensation structure, and a performance management system.

# The evolution of retirement plans 

Employee Pensions: Policies, Problems, $\mathcal{E}$ Possibilities. By Teresa Ghilarducci and Christian E. Weller, Eds., Ithaca, NY, Cornell University Press, 2008, 236 pp., \$29.95/paperback.

Retirement plans have changed and can be expected to continue to change. So, why have many employers made the switch from defined benefit to defined contribution plans? What might retirement plans look like in the future?
Retirement plans that we think of as traditional pensions are called defined benefit plans. They have a known benefit based on a formula that typically includes years of service, and may or may not be completely em-ployer-paid. Defined contribution plans are a more recent development. These are plans in which employees contribute, and the employer may or may not offer a matching contribution. With the defined contribution plans the amount of contribution is known, but the benefit payout is not.
Teresa Ghilarducci and Christian E. Weller have compiled nine articles discussing the changes companies have made to their pensions, suggestions to improve these plans, and pension policy in the United States. They include a good introduction, providing an overview of pension plan issues and the book's layout. The book is divided into four sections: Justification for the Employer-Based System, Getting Defined Benefit Plans Ready for the Future, Ways to Improve Defined Contribution Plans, and lastly, Understanding the Political Dimensions
of Pension Reform.
The first section, Justification for the Employer-Based System, focuses on the advantages of defined benefit retirement plans. Jeff Wenger and Laura D'Arcy describe how, for employees, these include a known benefit and, typically, greater retirement savings compared to defined contribution plans. Employers also benefit by being able to use defined benefit plans to adjust their labor force when needed; for example, offering higher returns for longer service to retain employees or subsidies for early retirement to downsize. An article by William Lazonick describes how employers changed from offering traditional, non-portable defined benefit plans to portable defined contribution plans because they transitioned to a new business model. Employers no longer had the expectation of lifelong employment and also needed to attract experienced workers. Lazonick includes several examples of companies in the information and communication technologies industries.
Getting Defined Benefit Plans Ready for the Future includes two articles that offer suggestions on what can be done to improve defined benefit plans. Sylvester Schieber proposes hybrid plans, which combine features of defined benefit and defined contribution plans, and would offer advantages to both employers and employees. Beth Almeida suggests multi-employer plans, in which employers group together to provide a defined benefit plan that is similar to the design of many union retirement plans.

Workers with defined contribution plans bear several risks, includ-
ing investment decisions and market returns. The articles included in Ways to Improve Defined Contribution Plans discuss the risks involved and ways to mitigate them. The risk of outliving retirement savings is further discussed in an article by Pamela Perun in which she proposes having an annuity option with defined contribution plans.
The last section of the book includes articles about Understanding the Political Dimensions of Pension Reform. An article by Michele Varnhagen provides a summary of the many policies and ensuing debates since the enactment of the Employee Retirement Income Security Act of 1974. David Madland then examines the responses of workers and retirees to pension cuts.
The editors, Teresa Ghilarducci and Christian E. Weller, conclude the book by summarizing the articles and their own opinions. They suggest reforms that would create retirement plans that have the best aspects of defined benefit and defined contribution plans.
This book will appeal to anyone interested in the context in which pension plans have changed and ideas on how current plans could be improved. Each article and each section of the book stands on its own, so the book can be read in whole or in part. The articles included are cohesive with some common themes repeating, yet each offers a unique contribution.

## Financial literacy

"True or false? Buying a company stock usually provides a safer return than a stock mutual fund." This question and others are asked to people age 18 and older in the Rand American Life Panel. In response to the aforementioned question, respondents can choose "true," "false," or "don't know." Only 71.4 percent of people answered "false," the correct answer, and 24.5 percent indicated they did not know. In the article "How Ordinary Consumers Make Complex Economic Decisions: Financial Literacy and Retirement Readiness," (NBER Working Paper Series, National Bureau of Economic Research, September 2009) Annamaria Lusardi and Olivia S. Mitchell discuss results from the Rand American Life Panel and other studies that have measured financial literacy in the United States.
The Rand American Life Panel poses basic questions to test whether or not respondents have at least a general sense of a number of financial concepts, and it also asks how much respondents have thought about retirement. There are simpler questions that ask about concepts such as compound interest and inflation, and more difficult questions that test whether respondents have a basic sense of concepts such as the stock market, mutual funds, bonds, volatility, and risk diversification. Although almost every question had a correct-response rate of more than 50 percent, less than half of respondents answered all of the five easier questions correctly and only 16.5 percent of respondents answered all eight of the more difficult questions correctly. Lusardi and Mitchell report that men, people 50 or older, and people with a college degree displayed higher levels of financial literacy and were more
likely to think about retirement than women, people younger than 50 , and people without a college degree, respectively.
There are also questions that ask people to rate their understanding of economics, to report how much economics they have learned in school, and to indicate whether or not their workplaces have offered financial education programs. On the whole, people who rated their own knowledge of economics highly, those who had taken economics in school, and those who had been offered financial education programs in the workplace all were more likely to score better on the financial literacy questions. Through the use of a multivariate analysis linking retirement planning to financial literacy, the authors determine that, even after controlling for a number of socioeconomic factors, people who attained higher scores on the questions testing financial literacy were more likely to have given serious thought to retirement.

## Measuring potential economic growth

How much do economists know about measuring potential economic output? That question is the theme of the July/August 2009 issue of the Federal Reserve Bank of St. Louis Revierw, in which seven papers presented at the Bank's 2008 policy conference are published. Measuring potential economic output-defined as the maximum sustainable level of output-is integral to maximizing employment while keeping prices stable. To make rational decisions, policymakers need to know the difference between actual and potential output (the "output gap") and they need to understand how and why the
actual rate of inflation often differs from the targeted rate.
Each of the articles in the July/August Review deals with some aspect of potential output growth and its measurement. The first two papers are highly theoretical: one addresses neoclassical growth models and argues that a two-sector model is preferable because technological shocks have different effects on investment goods and consumption goods; the second theoretical paper embeds a production function-which specifies total output for all combinations of inputs-within a dynamic stochastic general equilibrium model and argues that policymakers need models which enable them to compare flexible price concepts based on the production function approach with those based on the real business cycle approach.
Two of the papers deal with the effects of using "real-time" data in measuring potential output: one analyzes the role the output gap has played in Canadian monetary policy, particularly in relation to projections used by Canada's central bank; the second employs a state-space model to estimate the "true" unobserved measure of total output in the United States. Two of the papers use an empirical approach to measure potential output: one stresses that potential is less a "technological ceiling" than it is a measure of the maximum sustainable output; the other looks at the role of labor force trends in measuring potential output, particularly life expectancy, household net worth, and the unemployment rate. Finally, one of the papers examines the issue of measuring potential output in China, a rapidly developing country, compared with measuring potential output in the United States and the European Union.

This section of the Review presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

## General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables $1-14,17-21,48$, and 52 . Seasonally adjusted labor force data in tables 1 and 4-9 and seasonally adjusted establishment survey data shown in tables 1,12-14, and 17 are revised in the March 2007 Review. A brief explanation of the seasonal adjustment methodology appears in "Notes on the data."

Revisions in the productivity data in table 54 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average AllItems CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data-such as the "real" earnings shown in table 14 -are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100 . For example, given a current hourly wage rate of $\$ 3$ and a current price index number of 150 , where $1982=100$, the hourly rate expressed in 1982 dollars is $\$ 2(\$ 3 / 150$ $x 100=\$ 2$ ). The $\$ 2$ (or any other resulting
values) are described as "real," "constant," or "1982" dollars.

## Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see BLS Handbook of Methods, Bulletin 2490. Users also may wish to consult Major Programs of the Bureau of Labor Statistics, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau's monthly publication, Employment and Earnings. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:

> www.bls.gov/cps/

Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:
www.bls.gov/ces/
Additional information on labor force data for areas below the national level are provided in the BLS annual report, Geographic Profile of Employment and Unemployment.

For a comprehensive discussion of the Employment Cost Index, see Employment Cost Indexes and Levels, 1975-95, BLS Bulletin 2466 . The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: Employee Benefits in Medium and Large Firms; Employee Benefits in Small Private Establishments; and Employee Benefits in State and Local Governments.

More detailed data on consumer and producer prices are published in the monthly periodicals, The CPI Detailed Report and Producer Price Indexes. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the Monthly Labor Revier. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

## www.bls.gov/lpc/

For additional information on international comparisons data, see International Comparisons of Unemployment, Bulletin
1979.

Detailed data on the occupational injury and illness series are published in Occupational Injuries and Illnesses in the United States, by Industry, a BLS annual bulletin.

Finally, the Monthly Labor Review carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

## Comparative Indicators

## (Tables 1-3)

Comparative indicators tables provide an overview and comparison of major blS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on changes in compensation, prices, and productivity are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index
program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

## Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

## Employment and Unemployment Data

(Tables 1; 4-29)

## Household survey data

## Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

## Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work
because they were on layoff are also counted among the unemployed. The unemployment rate represents the number unemployed as a percent of the civilian labor force.

The civilian labor force consists of all employed or unemployed persons in the civilian noninstitutional population. Persons not in the labor force are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The civilian noninstitutional population comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The civilian labor force participation rate is the proportion of the civilian noninstitutional population that is in the labor force. The employment-population ratio is employment as a percent of the civilian noninstitutional population.

## Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of Employment and Earnings. For a discussion of changes introduced in January 2003, see "Revisions to the Current Population Survey Effective in January 2003" in the February 2003 issue of Employment and Earnings (available on the BLS Web site at www.bls.gov/cps/rvcps03.pdf).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See "Revision of Seasonally Adjusted Labor Force Series in 2003," in the February 2003 issue of Employment and Earnings (available on the BLS Web site at www.bls.gov/cps/cpsrs.pdf) for a discussion of the introduction of the use of X-12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the January-June period. The historical season-
ally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July-December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691-6378.

## Establishment survey data

## Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2002 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

## Definitions

An establishment is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12 th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goods-producing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private ser-vice-providing industries, data are collected for nonsupervisory workers, which include most employees except those in executive, managerial, and supervisory positions. Those
workers mentioned in tables 11-16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private service-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. Real earnings are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. Overtime hours represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6month spans are seasonally adjusted, while those for the 12 -month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

## Notes on the data

Establishment survey data are annually adjusted to comprehensive counts of employment (called "benchmarks"). The March 2003 benchmark was introduced in February 2004 with the release of data for January 2004, published in the March 2004 issue of the Revier. With the release in June 2003, CES completed a conversion from the Standard Industrial Classification (SIC) system to the North American Industry Classification System (NAICS) and completed the transition from its original quota sample design to a probability-based sample design. The indus-try-coding update included reconstruction of historical estimates in order to preserve
time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the June 2003 issue of Employment and Earnings and "Recent changes in the national Current Employment Statistics survey," Monthly Labor Revierw, June 2003, pp. 3-13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of Employment and Earnings, and "Recent changes in the State and Metropolitan Area CES survey," Monthly Labor Review, June 2003, pp. 14-19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4 - versus 5 -week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12-17 in the Review). When all returns have been received, the estimates are revised and published as "final" (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Fourth-quarter data are published as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on
establishment survey data, contact the Division of Current Employment Statistics: (202) 691-6555.

## Unemployment data by State

## Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

## Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691-6392 (table 10) or (202) 691-6559 (table 11).

## Quarterly Census of Employment and Wages

## Description of the series

Employment, wage, and establishment data in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal, agencies subject to the Unemployment Compensation for Federal Employees (ucfe) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Quarterly Census of Employment and Wages (QCEW) data, also referred as ES202 data, are the most complete enumeration of employment and wage information by industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor
market trends and major industry developments.

## Definitions

In general, the Quarterly Census of Employment and Wages monthly employment data represent the number of covered workers who worked during, or received pay for, the pay period that included the 12 th day of the month. Covered private industry employment includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each ui-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (UCFE) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An establishment is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different NAICS industries.

Most employers have only one establishment; thus, the establishment is the predominant reporting unit or statistical entity for reporting employment and wages
data. Most employers, including State and local governments who operate more than one establishment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly ui report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the uI report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the installation: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers. Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into size categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level. It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total wages paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify that wages be reported for, or based on the period during which services are performed
rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as $401(\mathrm{k})$ plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wage per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual wage is affected by the ratio of full-time to part-time workers as well as the number of individuals in high-paying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of part-time workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

## Notes on the data

Beginning with the release of data for 2001, publications presenting data from the Covered Employment and Wages program have switched to the 2002 version of the North American Industry Classification System
(NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Standard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past, the Covered Employment and Wage (CEW) program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England (and New Jersey).

The Office of Management and Budget (OMB) defines metropolitan areas for use
in Federal statistical activities and updates these definitions as needed. Data in this table use metropolitan area criteria established by OMB in definitions issued June 30, 1999 (OMB Bulletin No. 99-04). These definitions reflect information obtained from the 1990 Decennial Census and the 1998 U.S. Census Bureau population estimate. A complete list of metropolitan area definitions is available from the National Technical Information Service (NTIS), Document Sales, 5205 Port Royal Road, Springfield, Va. 22161, telephone 1-800-553-6847.

OMB defines metropolitan areas in terms of entire counties, except in the six New England States where they are defined in terms of cities and towns. New England data in this table, however, are based on a county concept defined by OMB as New England County Metropolitan Areas (NECMA) because coun-ty-level data are the most detailed available from the Quarterly Census of Employment and Wages. The NECMA is a county-based alternative to the city- and town-based metropolitan areas in New England. The NECMA for a Metropolitan Statistical Area (MSA) include: (1) the county containing the first-named city in that MSA title (this county may include the first-named cities of other MSA, and (2) each additional county having at least half its population in the MSA in which first-named cities are in the county identified in step 1. The NECMA is officially defined areas that are meant to be used by statistical programs that cannot use the regular metropolitan area definitions in New England.

For additional information on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691-6567.

## Job Openings and Labor Turnover Survey

## Description of the series

Data for the Job Openings and Labor Turnover Survey (JOLTS) are collected and compiled from a sample of 16,000 business establishments. Each month, data are collected for total employment, job openings, hires, quits, layoffs and discharges, and other separations. The JolTs program covers all private nonfarm establishments such as factories, offices, and stores, as well as Federal, State, and local government entities in the 50 States and the District of Columbia. The JOLTS sample design is a random sample drawn from a universe of more than eight million establishments compiled as part of the operations of the Quarterly Census of Em-
ployment and Wages, or QCEW, program. This program includes all employers subject to State unemployment insurance (UI) laws and Federal agencies subject to Unemployment Compensation for Federal Employees (UCFE).

The sampling frame is stratified by ownership, region, industry sector, and size class. Large firms fall into the sample with virtual certainty. JolTS total employment estimates are controlled to the employment estimates of the Current Employment Statistics (CES) survey. A ratio of CES to JOLTS employment is used to adjust the levels for all other JOLTS data elements. Rates then are computed from the adjusted levels.

The monthly JOLTS data series begin with December 2000. Not seasonally adjusted data on job openings, hires, total separations, quits, layoffs and discharges, and other separations levels and rates are available for the total nonfarm sector, 16 private industry divisions and 2 government divisions based on the North American Industry Classification System (NAICS), and four geographic regions. Seasonally adjusted data on job openings, hires, total separations, and quits levels and rates are available for the total nonfarm sector, selected industry sectors, and four geographic regions.

## Definitions

Establishments submit job openings in-for-mation for the last business day of the reference month. A job opening requires that (1) a specific position exists and there is work available for that position; and (2) work could start within 30 days regardless of whether a suitable candidate is found; and (3) the employer is actively recruiting from outside the establishment to fill the position. Included are full-time, part-time, permanent, short-term, and seasonal openings. Active recruiting means that the establishment is taking steps to fill a position by advertising in newspapers or on the Internet, posting help-wanted signs, accepting applications, or using other similar methods.

Jobs to be filled only by internal transfers, promotions, demotions, or recall from layoffs are excluded. Also excluded are jobs with start dates more than 30 days in the future, jobs for which employees have been hired but have not yet reported for work, and jobs to be filled by employees of temporary help agencies, employee leasing companies, outside contractors, or consultants. The job openings rate is computed by dividing the number of job openings by the sum of employment and job openings, and multiplying that quotient by 100 .

Hires are the total number of additions
to the payroll occurring at any time during the reference month, including both new and rehired employees and full-time and parttime, permanent, short-term and seasonal employees, employees recalled to the location after a layoff lasting more than 7 days, on-call or intermittent employees who returned to work after having been formally separated, and transfers from other locations. The hires count does not include transfers or promotions within the reporting site, employees returning from strike, employees of temporary help agencies or employee leasing companies, outside contractors, or consultants. The hires rate is computed by dividing the number of hires by employment, and multiplying that quotient by 100 .

Separations are the total number of terminations of employment occurring at any time during the reference month, and are reported by type of separation-quits, layoffs and discharges, and other separations. Quits are voluntary separations by employees (except for retirements, which are reported as other separations). Layoffs and discharges are involuntary separations initiated by the employer and include layoffs with no intent to rehire, formal layoffs lasting or expected to last more than 7 days, discharges resulting from mergers, downsizing, or closings, firings or other discharges for cause, terminations of permanent or short-term employees, and terminations of seasonal employees. Other separations include retirements, transfers to other locations, deaths, and separations due to disability. Separations do not include transfers within the same location or employees on strike.

The separations rate is computed by dividing the number of separations by employment, and multiplying that quotient by 100 . The quits, layoffs and discharges, and other separations rates are computed similarly, dividing the number by employment and multiplying by 100 .

## Notes on the data

The JOLTS data series on job openings, hires, and separations are relatively new. The full sample is divided into panels, with one panel enrolled each month. A full complement of panels for the original data series based on the 1987 Standard Industrial Classification (SIC) system was not completely enrolled in the survey until January 2002. The supple-mental panels of establishments needed to create NAICS estimates were not completely enrolled until May 2003. The data collected up until those points are from less than a full sample. Therefore, estimates from earlier months should be used with caution, as fewer sampled
units were reporting data at that time.
In March 2002, BLS procedures for collecting hires and separations data were revised to address possible underreporting. As a result, JOLTS hires and separations estimates for months prior to March 2002 may not be comparable with estimates for March 2002 and later.

The Federal Government reorganization that involved transferring approximately 180,000 employees to the new Department of Homeland Security is not reflected in the JOLTS hires and separations estimates for the Federal Government. The Office of Personnel Management's record shows these transfers were completed in March 2003. The inclusion of transfers in the JOLTS definitions of hires and separations is intended to cover ongoing movements of workers between establishments. The Department of Homeland Security reorganization was a massive one-time event, and the inclusion of these intergovernmental transfers would distort the Federal Government time series.

Data users should note that seasonal adjustment of the JOLTS series is conducted with fewer data observations than is customary. The historical data, therefore, may be subject to larger than normal revisions. Because the seasonal patterns in economic data series typically emerge over time, the standard use of moving averages as seasonal filters to capture these effects requires longer series than are currently available. As a result, the stable seasonal filter option is used in the seasonal adjustment of the JOLTS data. When calculating seasonal factors, this filter takes an average for each calendar month after detrending the series. The stable seasonal filter assumes that the seasonal factors are fixed; a necessary assumption until sufficient data are available. When the stable seasonal filter is no longer needed, other program features also may be introduced, such as outlier adjustment and extended diagnostic testing. Additionally, it is expected that more series, such as layoffs and discharges and additional industries, may be seasonally adjusted when more data are available.

JolTs hires and separations estimates cannot be used to exactly explain net changes in payroll employment. Some reasons why it is problematic to compare changes in payroll employment with JOLTS hires and separations, especially on a monthly basis, are: (1) the reference period for payroll employment is the pay period including the 12 th of the month, while the reference period for hires and separations is the calendar month; and (2) payroll employment can vary from month to month simply because part-time and oncall workers may not always work during
the pay period that includes the 12th of the month. Additionally, research has found that some reporters systematically underreport separations relative to hires due to a number of factors, including the nature of their payroll systems and practices. The shortfall appears to be about 2 percent or less over a 12-month period.

FOR ADDITIONAL INFORMATION on the Job Openings and Labor Turnover Survey, contact the Division of Administrative Statistics and Labor Turnover at (202) 961-5870.

## Compensation and Wage Data

(Tables 1-3; 30-37)
The National Compensation Survey (NCS) produces a variety of compensation data. These include: The Employment Cost Index (ECI) and NCS benefit measures of the incidence and provisions of selected employee benefit plans. Selected samples of these measures appear in the following tables. NCS also compiles data on occupational wages and the Employer Costs for Employee Compensation (ECEC).

## Employment Cost Index

## Description of the series

The Employment Cost Index (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It is a Laspeyres Index that uses fixed employment weights to measure change in labor costs free from the influence of employment shifts among occupations and industries.

The ECI provides data for the civilian economy, which includes the total private nonfarm economy excluding private households, and the public sector excluding the Federal government. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Sample establishments are classified by industry categories based on the 2002 North American Classification System (NAICS). Within a sample establishment, specific job categories are selected and classified into about 800 occupations according to the 2000 Standard Occupational Classification (SOC) System. Individual occupations are combined to represent one of ten intermediate aggregations, such as professional and related occupations, or one of five higher level aggre-
gations, such as management, professional, and related occupations.

Fixed employment weights are used each quarter to calculate the most aggregate series-civilian, private, and State and local government. These fixed weights are also used to derive all of the industry and occupational series indexes. Beginning with the March 2006 estimates, 2002 fixed employment weights from the Bureau's Occupational Employment Statistics survey were introduced. From March 1995 to December 2005, 1990 employment counts were used. These fixed weights ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the series based on bargaining status, census region and division, and metropolitan area status, fixed employment data are not available. The employment weights are reallocated within these series each quarter based on the current ECI sample. The indexes for these series, consequently, are not strictly comparable with those for aggregate, occupational, and industry series.

## Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

## Notes on the data

The ECI data in these tables reflect the con-version to the 2002 North American Industry Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. ECI series based on NAICS and SOC became the official BLS estimates starting in March 2006.

The ECI for changes in wages and salaries in the private nonfarm economy was published beginning in 1975. Changes in total compensation cost-wages and salaries and
benefits combined-were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (December $2005=100$ ) are available on the Internet: www.bls.gov/ect/

ADDITIONAL INFORMATION on the Employment Cost Index is available at www. bls.gov/ncs/ect/home.htm or by telephone at (202) 691-6199.

## National Compensation Survey Benefit Measures

## Description of the series

NCS benefit measures of employee benefits are published in two separate reports. The annual summary provides data on the incidence of (access to and participation in) selected benefits and provisions of paid holidays and vacations, life insurance plans, and other selected benefit programs. Data on percentages of establishments offering major employee benefits, and on the employer and employee shares of contributions to medical care premiums also are presented. Selected benefit data appear in the following tables. A second publication, published later, contains more detailed information about health and retirement plans.

## Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Employees are considered as having access to a benefit plan if it is available for their use. For example, if an employee is permitted to participate in a medical care plan offered by the employer, but the employee declines to do so, he or she is placed in the category with those having access to medical care.

Employees in contributory plans are considered as participating in an insurance or retirement plan if they have paid required contributions and fulfilled any applicable service requirement. Employees in noncontributory plans are counted as participating
regardless of whether they have fulfilled the service requirements.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

## Notes on the data

AdDITIONAL INFORMATION ON THE NCS benefit measures is available at www.bls. gov/ncs/ebs/home.htm or by telephone at (202) 691-6199.

## Work stoppages

## Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 37.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

## Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of esti-
mated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

## Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

ADDITIONAL INFORMATION on work stop-pages data is available at www. bls. gov/cba/home.htm or by telephone at (202) 691-6199.

## Price Data

(Tables 2; 38-46)
Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base pe-riod-December 2003 = 100 for many Producer Price Indexes (unless otherwise noted), 1982-84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 $=100$ for International Price Indexes.

## Consumer Price Indexes

## Description of the series

The Consumer Price Index (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993-95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, shortterm workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors'
and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S.city average." Separate estimates for 14 major urban centers are presented in table 39.The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

## Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are meaured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691-7000.

## Producer Price Indexes

## Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in accordance with the 2002 North American Industry Classification System and product codes developed by the U.S. Census Bureau.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691-7705.

## International Price Indexes

## Description of the series

The International Price Program produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first week of the month. Survey respondents are asked to indicate all discounts, allow-
ances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard International Trade Classification (SITC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

## Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000 .

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691-7155.

## Productivity Data

(Tables 2; 47-50)

## Business and major sectors

## Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour, output per unit of labor input, or output per unit of capital input, as well as measures of
multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

## Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. Output per unit of capital services (capital productivity) is the quantity of goods and services produced per unit of capital services input. Multifactor productivity is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). Real compensation per hour is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. Unit nonlabor payments include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets-equipment, structures,
land, and inventories-weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

## Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 47-50 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity, energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

FOR ADDITIONAL INFORMATION on this productivity series, contact the Division of Productivity Research: (202) 691-5606.

## Industry productivity measures

## Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

## Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, output indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The labor input series is based on the hours of all workers or, in the case of some transportation industries, on the number of employees. For most industries, the series consists of the hours of all employees. For some trade and services industries, the series also includes the hours of partners, proprietors, and unpaid family workers.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. Labor compensation includes payroll as well as supplemental payments, including both legally required expenditures and payments for voluntary programs.

Multifactor productivity is derived by dividing an index of industry output by an index of combined inputs consumed in producing that output. Combined inputs include capital, labor, and intermediate purchases. The measure of capital input represents the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets-equipment, structures, land, and inventories. The measure of intermediate purchases is a combination of purchased materials, services, fuels, and electricity.

## Notes on the data

The industry measures are compiled from
data produced by the Bureau of Labor Statistics and the Census Bureau, with additional data supplied by other government agencies, trade associations, and other sources.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Industry Productivity Studies: (202) 691-5618, or visit the Web site at: www.bls.gov/lpc/home.htm

## International Comparisons

(Tables 51-53)

## Labor force and unemployment

## Description of the series

Tables 51 and 52 present comparative measures of the labor force, employment, and unemployment approximating U.S. concepts for the United States, Canada, Australia, Japan, and six European countries. The Bureau adjusts the figures for these selected countries, for all known major definitional differences, to the extent that data to prepare adjustments are available. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For further information on adjustments and comparability issues, see Constance Sorrentino, "International unemployment rates: how comparable are they?" Monthly Labor Review, June 2000, pp. 3-20, available on the Internet at www. bls.gov/opub/mlr/2000/06/art1full.pdf.

## Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

## Notes on the data

Foreign country data are adjusted as closely as possible to the U.S. definitions. Primary areas of adjustment address conceptual differences in upper age limits and definitions of employment and unemployment, provided that reliable data are available to make these adjustments. Adjustments are made where applicable to include employed and unemployed persons above upper age limits; some European countries do not include persons older than age 64 in their labor force measures, because a large portion of this population has retired. Adjustments are made to exclude active duty military from employment figures, although a small
number of career military may be included in some European countries. Adjustments are made to exclude unpaid family workers who worked fewer than 15 hours per week from employment figures; U.S. concepts do not include them in employment, whereas most foreign countries include all unpaid family workers regardless of the number of hours worked. Adjustments are made to include full-time students seeking work and available for work as unemployed when they are classified as not in the labor force.

Where possible, lower age limits are based on the age at which compulsory schooling ends in each country, rather than based on the U.S. standard of 16 . Lower age limits have ranged between 13 and 16 over the years covered; currently, the lower age limits are either 15 or 16 in all 10 countries.

Some adjustments for comparability are not made because data are unavailable for adjustment purposes. For example, no adjustments to unemployment are usually made for deviations from U.S. concepts in the treatment of persons waiting to start a new job or passive job seekers. These conceptual differences have little impact on the measures. Furthermore, BLS studies have concluded that no adjustments should be made for persons on layoff who are counted as employed in some countries because of their strong job attachment as evidenced by, for example, payment of salary or the existence of a recall date. In the United States, persons on layoff have weaker job attachment and are classified as unemployed.

The annual labor force measures are obtained from monthly, quarterly, or continuous household surveys and may be calculated as averages of monthly or quarterly data. Quarterly and monthly unemployment rates are based on household surveys. For some countries, they are calculated by applying annual adjustment factors to current published data and, therefore, are less precise indicators of unemployment under U.S. concepts than the annual figures. The labor force measures may have breaks in series over time due to changes in surveys, sources, or estimation methods. Breaks are noted in data tables.

For up-to-date information on adjustments and breaks in series, see the Technical Notes of Comparative Civilian Labor Force Statistics, 10 Countries, on the Internet at www.bls.gov/fls/flscomparelf.htm, and the Notes of Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted, on the Internet at www.bls.gov/fls/flsjec.pdf.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Foreign Labor Statistics: (202) 691-5654 or flshelp@ bls.gov.

## Manufacturing productivity and labor costs

## Description of the series

Table 53 presents comparative indexes of manufacturing output per hour (labor productivity),output, total hours, compensation per hour, and unit labor costs for the United States, Australia, Canada, Japan, the Republic of Korea,Singapore,Taiwan, and 10 European countries. These measures are trend compari-sons-that is, series that measure changes over time-rather than level comparisons. BLS does not recommend using these series for level comparisons because of technical problems.

BLS constructs the comparative indexes from three basic aggregate measures-output, total labor hours, and total compensation. The hours and compensation measures refer to employees (wage and salary earners) in Belgium and Taiwan. For all other economies, the measures refer to all employed persons, including employees, self-employed persons, and unpaid family workers.

The data for recent years are based on the United Nations System of National Accounts 1993 (SNA 93). Manufacturing is generally defined according to the International Standard Industrial Classification (ISIC). However, the measures for France include parts of mining as well. For the United States and Canada, manufacturing is defined according to the North American Industry Classification System (NAICS 97).

## Definitions

Output. For most economies, the output measures are real value added in manufacturing from national accounts. However, output for Japan prior to 1970 and for the Netherlands prior to 1960 are indexes of industrial production. The manufacturing value added measures for the United Kingdom are essentially identical to their indexes of industrial production.

For United States, the output measure for the manufacturing sector is a chain-weighted index of real gross product originating (deflated value added) produced by the Bureau of Economic Analysis of the U.S. Department of Commerce. Most of the other economies now also use chain-weighted as opposed to fixed-year weights that are periodically updated.

To preserve the comparability of the U.S. measures with those of other economies, BLS uses gross product originating in manufacturing for the United States. The gross product originating series differs from the manufacturing output series that BLS pub-
lishes in its quarterly news releases on U.S productivity and costs (and that underlies the measures that appear in tables 48 and 50 in this section). The quarterly measures are on a "sectoral output" basis, rather than a valueadded basis. Sectoral output is gross output less intrasector transactions.

Total hours refer to hours worked in all economies. The measures are developed from statistics of manufacturing employment and average hours. For most other economies, recent years' aggregate hours series are obtained from national statistical offices, usually from national accounts. However, for some economies and for earlier years, BLS calculates the aggregate hours series using employment figures published with the national accounts, or other comprehensive employment series, and data on average hours worked.

Hourly compensation is total compensation divided by total hours. Total compensation includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. For Australia, Canada, France, Singapore, and Sweden, compensation is increased to account for important taxes on payroll or employment. For the United Kingdom, compensation is reduced between 1967 and 1991 to account for subsidies.

Labor productivity is defined as real output per hour worked. Although the labor productivity measure presented in this release relates output to the hours worked of persons employed in manufacturing, it does not measure the specific contributions of labor as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology, capital investment, capacity utilization, energy use, and managerial skills, as well as the skills and efforts of the workforce.

Unit labor costs are defined as the cost of labor input required to produce one unit of output. They are computed as compensation in nominal terms divided by real output. Unit labor costs can also be computed by dividing hourly compensation by output per hour, that is, by labor productivity.

## Notes on the data

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

FOR ADDITIONAL INFORMATION on this series, go to http://www.bls.gov/news. release/prod4.toc.htm or contact the Divi-
sion of International Labor Comparison at (202) 691-5654.

## Occupational Injury and IIIness Data

(Tables 54-55)

## Survey of Occupational Injuries and IIInesses

## Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers' job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

## Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both,
because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

## Notes on the data

The definitions of occupational injuries and illnesses are from Recordkeeping Guidelines for Occupational Injuries and Illnesses (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent
full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, Occupational Injuries and Illnesses: Counts, Rates, and Characteristics.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to bls by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691-6180, or access the Internet at: www.bls. gov/iif/

## Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety
and Health Administration records, medical examiner and autopsy reports, media accounts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

## Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses,which can be difficult to identify due to long latency periods.

## Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 6916175, or the Internet at: www.bls.gov/iif/

${ }^{1}$ Quarterly data seasonally adjusted.
${ }^{2}$ Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter.
${ }^{3}$ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and soc data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.
${ }^{4}$ Excludes Federal and private household workers.
${ }^{5}$ Goods-producing industries include mining, construction, and manufacturing. Serviceproviding industries include all other private sector industries.

NOTE: Beginning in January 2003, household survey data reflect revised population controls. Nonfarm data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with sIC based data.
2. Annual and quarterly percent changes in compensation, prices, and productivity

${ }^{1}$ Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter. Compensation and price data are not seasonally adjusted, and the price data are not compounded.
${ }^{2}$ Excludes Federal and private household workers.
${ }^{3}$ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes
only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.
${ }^{4}$ Annual rates of change are computed by comparing annual averages. Quarterly percent changes reflect annual rates of change in quarterly indexes. The data are seasonally adjusted.
${ }^{5}$ Output per hour of all employees.
3. Alternative measures of wage and compensation changes

1 Seasonally adjusted. "Quarterly average" is percent change from a quarter ago, at an annual rate.
${ }^{2}$ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard

Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.
3 Excludes Federal and private household workers.
4. Employment status of the population, by sex, age, race, and Hispanic origin, monthly data seasonally adjusted

4. Continued-Employment status of the population, by sex, age, race, and Hispanic origin, monthly data seasonally adjusted
[Numbers in thousands]

${ }^{1}$ The population figures are not seasonally adjusted.
${ }^{2}$ Civilian employment as a percent of the civilian noninstitutional population.
${ }^{3}$ Beginning in 2003, persons who selected this race group only; persons who selected more than one race group are not included. Prior to 2003, persons who reported more than one race were included in the group they identified as the main race.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in January 2003, data reflect revised population controls used in the household survey.

${ }^{1}$ Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs.
${ }^{2}$ Includes data for Metropolitan Statistical Areas (MSA) as defined by OMB Bulletin No. 04-03 as of February 18, 2004.
${ }^{3}$ Each year's total is based on the MSA definition for the specific year. Annual changes include differences resulting from changes in MSA definitions.
${ }^{4}$ Totals do not include the six MSAs within Puerto Rico.
27. Annual data: Employment status of the population
[Numbers in thousands]

| Employment status | $1998{ }^{1}$ | $1999{ }^{1}$ | $2000^{1}$ | $2001{ }^{1}$ | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

[^17]34. Continued-National Compensation Survey: Retirement benefits in private industry by access, participation, and selected series, 2003-2007

${ }^{1}$ The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC)
System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.
${ }^{2}$ The white-collar and blue-collar occupation series were discontinued effective 2007.
${ }^{3}$ The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.

Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

${ }^{1}$ The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC)
System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.
${ }^{2}$ The white-collar and blue-collar occupation series were discontinued effective 2007.
${ }^{3}$ The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.
36. National Compensation Survey: Percent of workers in private industry with access to selected benefits, 2003-2007

${ }^{1}$ Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:
M-Every month.
1-January, March, May, July, September, and November
2-February, April, June, August, October, and December
${ }^{2}$ Regions defined as the four Census regions.
${ }^{3}$ Indexes on a December $1996=100$ base
${ }^{4}$ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.
${ }^{5}$ Indexes on a December $1986=100$ base.
${ }^{6}$ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the CPI Detailed

Report: Anchorage, AK; Cincinnatti, OH-KY-IN; Kansas City, MO-Ks; Milwaukee-Racine, WI; Minneapolis-St. Paul, MN-WI; Pittsburgh, PA; Port-land-Salem OR-WA; St Louis, MO-IL; San Diego, CA; Tampa-St. Petersburg-Clearwater, FL
${ }^{7}$ Indexes on a November $1996=100$ base.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Each loca index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date. Dash indicates data not available.

NOTE: Dash indicates data not available
Quarterly figures for France, Germany, Italy, and the Netherlands are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures. Quarterly figures for Sweden are BLS seasonally adjusted estimates derived from Swedish not seasonally adjusted data. For further qualifications and historical annual data, see the BLS report International comparisons of annual labor force statistics, 10 countries (on the internet at
http://www.bls.gov/fls/flscomparelf.htm). For monthly unemployment rates, as well as the quarterly and annual rates published in this table, see the BLS report Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted (on the Internet at http://www.bls.gov/fls/flsjec.pdf), Unemployment rates may differ between the two reports mentioned, because the former is updated annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.
52. Annual data: employment status of the working-age population, approximating U.S. concepts, 10 countries

${ }^{1}$ Data for 1989 and subsequent years are based on the Standard Industrial Classification Manual, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985-88, which were based on the Standard Industrial Classification Manual, 1972 Edition, 1977 Supplement
${ }^{2}$ Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fata Occupational Injuries
${ }^{3}$ The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where
$\mathrm{N}=$ number of injuries and illnesses or lost workdays;
EH = total hours worked by all employees during the calendar year; and
$200,000=$ base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks
per year).
${ }^{4}$ Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.
${ }^{5}$ Excludes farms with fewer than 11 employees since 1976.
NOTE: Dash indicates data not available
55. Fatal occupational injuries by event or exposure, 1996-2005
