MONTHLY LABOR
REVIEW

Departments

The December *Review*

Our yearend issue for 2008 contains a rich variety of articles that summarize, in each case, years of research intended to shed light on how businesses come and go, how they operate, and which of their activities might most likely be shifted overseas.

We begin this month with a focus on a topic of perennial interest for observers of "job creation" and "job destruction," namely, the measurement of business "births" and "deaths" for entire firms or individual business establishments. Akbar Sadeghi describes the culmination of more than 2 years of research on the development of methods and concepts that are designed to illuminate aspects of business formation and survival. The dynamism of the United States economy is legendary, and data from the Bureau of Labor Statistics Business Employment Dynamics program have served to flesh out an empirical portrait of precisely how job gains and losses relate to business births and deaths. The alternative definitions and methods described in the article provide another step forward in our understanding of this vitally important subject, a topic all the more relevant given current events in the Nation's—and, indeed, the world's—labor markets.

How do young adults spend their money? And how does this affect their economic status? Geoffrey Paulin examines data from the Consumer Expenditure Survey for this important demographic group (single, never-married persons aged 21 to 29 years), who typically are facing the challenges of starting careers, establishing initial financial footholds, and determining what kinds of purchases are essential at this stage in their lives. He deepens his analysis by comparing spending patterns for this target group in recent years with their counterparts in the mid-1980s, and ponders just which group might be considered better or worse off economically.

In an attempt to shed more light on how workplaces and industries are changing, a classification system has been developed that describes basic business processes of firms and the business functions that are associated with those processes. As Sharon P. Brown describes, this system is now being used in the BLS Mass Layoff Statistics (MLS) program. The system is derived from existing literature on business processes, models of firms' activities, current research on outsourcing, the results of a feasibility study conducted by the program, and the program's ongoing collection of relevant information. In this article, mass layoff events are examined in light of changes in specific business functions, such as human resources management.

In a somewhat similar vein, Roger J. Moncarz, Michael G. Wolf, and Benjamin Wright summarize efforts that have been underway for a number of years to identify service-providing occupations that might be susceptible to "offshoring." They describe a system designed to identify characteristics that make an occupation vulnerable, and then they review past and projected patterns of employment and wages for 160 such jobs.

Recession and involuntary part-time work

A committee of economists affiliated with the National Bureau of Economic Research recently declared that the U.S. economy entered into a recession in December 2007. Various national labor market measures clearly support this conclusion. The unemployment rate, for instance, rose from 4.9 percent to 7.2 percent during the year ending in December 2008, and nonfarm payroll employment declined by 2.6 million.

Some labor market measures weakened even before the onset of the "official" recession, a phenomenon that is not atypical. The aforementioned jobless rate began edging up in mid-2007, and the share of the working-age population that is employed began trending down from its most recent peak 2 years ago. Another important indicator of labor market difficulty—the number of persons working part time for economic reasons—began to signal in about mid-2006 that the business cycle might be heading for a downturn. As a recent BLS report notes, it is not uncommon for this indicator of unfavorable business conditions to rise during periods of slackening demand for labor. Sometimes referred to as involuntary workers, persons working part time for economic reasons want full-time jobs but currently are unable to find full-time work or have had their hours cut back. The recent rise in involuntary part-time employment thus far has been due mainly to the latter circumstance. The rise has occurred mostly among workers aged 25 years and older. Workers employed in certain industries, particularly construction, food services, and retail trade, have borne the brunt of the increase.

The report discussing these and other findings derived from Current Population Survey data can be found at **www.bls.gov/opub/ils/pdf/opbils71.pdf** ☐

The births and deaths of business establishments in the United States

Bureau of Labor Statistics economists have tested various methods for defining and counting births and deaths of establishments and businesses; the results of their research will allow BLS to better measure entrepreneurship in the United States

Akbar Sadeghi

The role of entrepreneurs in the American economy is legendary. One of the unique characteristics of the U.S. economic system is the freedom to start a business relatively easily and quickly. Indeed, one of the engines of growth is the employment and wages generated by new businesses. It is also an economic reality that businesses close frequently. The interplay of business births and deaths is not fully understood with the existing range of economic measures available from U.S. statistical agencies.

The story of entrepreneurship also entails a neverending search for new and imaginative ways to combine the factors of production into new methods, processes, technologies, products, or services. These efforts lead to the growth of new businesses, the decline of less productive ones, and the reallocation of resources from less profitable businesses and establishments to more profitable ones. This process is often referred to as "creative destruction," a concept popularized by the economist Joseph Schumpeter.[1]

This article describes more than 2 years of research and development of concepts and methods. These findings lead towards a greater understanding of the role and dynamics of business formations and business deaths, of business survival, and of the changing contribution of American entrepreneurs. This work is expected to lead to the publication of new data series with quarterly estimates of business births and deaths under the BLS Business Employment Dynamics (BED) program, an outgrowth of the Quarterly Census of Employment and Wages (QCEW) program. In this article, the terms "births" and "deaths" refer to the births and deaths of entire firms or individual establishments. When the word "business" is used in the context of this article, it refers to both establishments and firms. However, establishment births and deaths are the article's main focus.

The BED statistics are based on measurement of "gross job flows." Data development and economic analysis based on job flows are a new approach in labor market analysis that came about primarily through access to the microdata of U.S. business establishments.[2] Over the past decade, researchers utilized data sources such as the QCEW and the Census Bureau's longitudinal database for the manufacturing sector to create a rich body of literature on this subject.[3] Gross job flows are estimated by simply aggregating the net changes in employment at the establishment level. Gross job gains are the sum of all net gains in expanding and opening establishments. Gross job losses, similarly, are the sum of all net losses in contracting and closing establishments. The net change in employment is the difference between gross job gains and gross job losses. Gross job gains and gross job losses are indica-

tive of job churn, and they reflect adjustments made by businesses in response to changes in economic events and conditions.

For the purposes of BED statistics, openings are defined as those establishments that had positive employment for the first time in the third month of the current quarter with no link to the previous quarter, or had positive employment in the current quarter and zero or no employment in the previous quarter.[4] "Zero employment" means that an employment level of zero was reported, whereas "no employment" means that there were not any employment numbers reported at all. In this article, the term "zero employment" is used to mean either zero employment or no employment. According to the BLS definition of openings, openings include both new startups (births) and reopenings of the existing seasonal establishments that reported zero employment in the previous quarter. Closings are defined in an analogous manner. Closings are establishments that reported positive employment in the third month of the previous quarter and zero employment in the current quarter. Closings include establishments that go out of business permanently (deaths), as well as seasonal businesses that shut down temporarily.

The concepts of establishment birth and establishment death—both of which exclude seasonal businesses—are highly significant for understanding the job market and the business cycle. Birth data provide a measure of entrepreneurial activities and gauge new entries and reallocation of resources towards growing areas. Births are entirely different from reopenings of existing businesses, which are included in current BED data on openings. Similarly, business death data measure failing enterprises and identify sectors from which resources are being shifted away. That again is different from the temporary plant shutdowns included in BED closings data. This article provides preliminary tabulations of business births and deaths and offers a methodology based on an analysis of the proposed definitions of birth and death. In what follows, first a brief overview of the Business Employment Dynamics concept, definitions and methodology is presented, followed by an analysis of the data on births and deaths that are based on the preferred method of estimation. Finally, alternative definitions of birth and death are discussed using birth and death estimates from the third quarter of 1994 through the first quarter of 2007.

What are Business Employment Dynamics?

The BED program publishes quarterly statistics on gross job gains and gross job losses. These statistics are derived from establishment-level microrecords of the QCEW program. The QCEW program's estimates are based on mandatory quarterly reports on employment and wages submitted by all employers subject to unemployment insurance laws. The quarterly reports are only the starting point. The incoming UI data are reviewed and edited, industry codes are assigned and routinely updated, geographical codes are assigned and updated, employment and wage data are scrutinized, respondents are contacted to validate significant changes in employment, predecessors and successors are identified, and corrections are made on the basis of new information. This value-added process turns raw, unedited administrative data into high-quality, reliable, and consistent economic statistics. The resulting QCEW statistics are the most accurate, timely, and frequent in the Federal statistical system at the local level. Each year, more than 850,000 records of newly born establishments are captured, coded and researched for predecessor and successor relationships. In the fourth quarter of 2007, the QCEW program reported an employment level of 137.0 million in 9.1 million establishments for the total U.S. private and public sectors.

The data gathered in the QCEW program provide a virtual census of employees on nonfarm payrolls, covering 98 percent of such employees. In addition to being an accurate and detailed source of employment statistics, QCEW serves as the sampling frame for numerous BLS surveys, as a benchmark for BLS's critical Current Employment Statistics and Occupational Employment Statistics surveys, and as an input to the Bureau of Economic Analysis' National Income and Product Accounts.

The QCEW records are matched across quarters to create a longitudinal history for each establishment. Records are linked by their unique identifiers, including State codes, unemployment insurance numbers, and reporting unit numbers. The linkage method is designed in such a way as to create a history for continuous records and identify entries and exits, while avoiding spurious births and deaths that could be reported in the event of any changes of ownership, mergers, acquisitions, spinoffs, or other corporate restructuring.

The longitudinal database created from the linked records is used to construct BED data, including employment levels and counts of establishments at opening, expanding, closing, and contracting businesses. Employment figures can also be aggregated by an employer's Employer Identification Number to measure BED data at the firm level. During the tabulation process, the employment reported in the third month of each consecutive quarter is used to measure the over-the-quarter employment change. The

sum of employment at the opening establishments and the change in employment of the expanding establishments is gross job gains. Similarly, the sum of the prior-quarter employment at the establishments that closed in the current quarter and the change in employment of the contracting establishments is gross job losses. The net employment growth for all firms can be measured in one of two ways: as the difference between total employment in the current and previous quarters or as the difference between gross job gains and gross job losses in the current quarter.

Business births

Although the concept of business births seems self-explanatory, in practice, measuring business births and deaths raises a number of definitional issues that have to be resolved. One issue is related to timing—that is, when a birth actually occurs. New businesses go through different phases. A new business often starts with an idea in the mind of an entrepreneur, then emerges in a home office setting with only the founder or founders as employees, and finally reaches the point at which it hires additional labor. One important question is whether births should be identified and measured at the point at which employees are hired or sometime prior to that. In a similar vein, another question is whether the "employment" concept or the "employee" concept should be the basis for identifying and measuring births. If employment is the basis, then self-employed people should be counted when measuring births. EUROSTAT, the statistical arm of the European Union, recommends this approach and thus includes entrepreneurs who have not hired any additional employees in their estimation of births. By contrast, the Organization for Economic Cooperation and Development uses only enterprises with hired employees as the basis for birth counts.

In some European countries, in response to a certain public policy, a large number of self-employed unincorporated enterprises regularly convert to formal corporations and become employers with one employee. This conversion distorts birth data that are based on the concept of having no employment in one period and having one or more employees in the next period. For that reason, the Organization for Economic Cooperation and Development initially recommended a two-employee threshold as another birth concept and referred to it as "economic birth." It was eventually decided that the threshold would be an establishment with one employee, and this concept was incorporated into the final version of the Manual on Business Demography Statistics.[5]

Another methodological issue in defining births is the distinction between births and entries. Births are defined as the creation of a combination of new factors of production such as organization, fixed assets, employment, and so on. Entries, by contrast, include, in addition to births, events such as mergers and takeovers as well as reactivation, relocation and industrial reclassification of existing businesses. Birth estimates can change as the result of the inclusion or exclusion of any of these events that change the demography of businesses.

In the United States, the Census Bureau's Statistics of U.S. Businesses publishes annual series with data similar to the BED quarterly data from a longitudinal database called Business Information Tracking System.[6] However, the Census Bureau's definitions of terms related to births and deaths differ from BLS definitions. Census annual estimates of births exclude self-employment. Statistics of U.S. Businesses defines births as "establishments that have zero employment in the first quarter of the initial year and positive employment in the first quarter of the subsequent year."[7] When births are estimated from March to March, this definition is similar to BED's definition of openings. According to the Census Bureau, entries are equal to new births plus reentries of temporarily inactive establishments. However, an establishment that reopens a few months into the year and then shuts down again before the end of the year would not be counted as a reentry.

Deaths are defined as "establishments that have positive employment in the first quarter of the initial year and zero employment in the first quarter of the subsequent year."[8] This definition is equivalent to BED's annual closings estimates. Exits are deaths plus temporary exits. An establishment that closes a few months into the year and then opens again before the end of the year would not be counted as a temporary exit. Thus, the Census definitions of entries and exits—like BED's definitions of openings and closings that are based on annual data—eliminate most, but not all, temporary openings and closings. Some establishments that are considered births or deaths according to Statistics of U.S. Businesses could be seasonal businesses that happened to have zero employment in the March of the reference year.[9]

James R. Spletzer estimated the contribution of births and deaths to economic growth by using microdata on all establishments in the State of West Virginia.[10] He defined net employment growth as the difference between total jobs created by births and expansions and total jobs destroyed by deaths and contractions. Births were defined as occurring during the first quarter of positive employment,

and deaths were defined as occurring during the last quarter of positive employment. Spletzer showed the contrast between those definitions of birth and death and an alternative definition in which births and deaths were designated as the first appearance and disappearance of records in the longitudinal database. The source of the difference was the inclusion of the establishments that reported zero employment at some point in their life cycle. In his analysis, Spletzer showed how alternative definitions of terms can aid in understanding the establishment's life cycle and its hazard function—defined as the likelihood of failure for an establishment over a given length of time.

The counts of births and deaths in this article are derived from the BED longitudinally linked database. Self-employed entities are not in the scope of BED data. In addition, establishments with zero employment are excluded from the counts of openings, and records are considered to be continuous in the events of mergers, acquisitions, and changes of ownership, as well as in the events of breakout and consolidation of multiworksite establishments. In addition, industrial reclassification of businesses and relocation of establishments within the States have no impact on the number of openings and closings. However, the reactivation of business units, the length of time between deactivation and reactivation, and the "unit of analysis" (firm or establishment) all have measurable effects on birth and death estimates.

This article defines births as those records that had positive employment in the third month of a quarter and zero employment in the third month of the previous four quarters. This definition includes all records with positive employment that appear in the BED database for the first time—as well as those records that were inactive for longer than five quarters—but excludes seasonal businesses that reappeared with positive employment within the last five quarters. The article defines a death as a unit that reported zero employment in the third month of a quarter and did not report positive employment in the third months of the next four quarters. This definition is symmetric to the birth definition.

Entrepreneurial birth

Births can be estimated at the *establishment* (plant) level or at the *firm* level. An establishment represents an economic unit that produces goods and services, usually at a single location, and engages in only one or predominantly one activity. A firm, on the other hand, may consist of several establishments. When an establishment opens for business for the first time, it is counted as an establishment

birth, a State-level firm birth, and a national-level firm birth. If the firm in question opens another establishment, this will be counted as another establishment birth and as a firm-level expansion. If that establishment is in another State, it also will be a counted as a State-level firm birth.

National firm-level births are more indicative of entrepreneurship than establishment-level births. Births at the firm level are referred to as entrepreneurial births; they measure strictly new business creation and the spread of entrepreneurship and innovative activities. Firm-level births were estimated at BLS by aggregating establishment birth records using the corporate parent's Employer Identification Number (EIN). The aggregated birth records were merged with the previous quarter's EIN records, and new EINs were looked for in birth records. EINs are generally the same across all units in multiunit businesses. The aggregation was done at the State and national level, and two sets of estimates for firm-level births were estimated. These different measures of business entries are shown in charts 1 and 2. Some facts stand out from changes revealed in these charts:

1. All measures of births follow the same pattern of change over time, which covers periods of expansion, recession, and recovery during the business cycle.

2. The number of jobs created by openings and births has trended downward since the first quarter of 1998.

3. The number of birth units generally follows an upward trend. The latest upsurge started from September 2003, a month during the quarter in which the net change in employment turned positive for the first time since the official end of the 2001 recession.

Establishment births

There were 201,681 establishment births in the fourth quarter of 2007, creating 858,997 jobs. (See table 1.) Seasonally adjusted, the number of establishment births per quarter exhibits an upward trend, whereas employment created by births is on a declining path. (See the smoothed lines in chart 3.) These trends mean a reduction in the average size of new startup businesses. Why is the average size of the new businesses shrinking? One possible explanation is the spread of new technologies and the ensuing rise in productivity that help all firms in general and new startup enterprises in particular. Changes in the average size of births are plotted against changes in the multifactor productivity[11] index in chart 4. The chart shows that the declining average number of employees in new businesses corresponds with the rising level of productivity. It seems that, on the basis of the limited number of observations

for the birth data, there is a correlation between the rise in productivity and the decline in the average size of establishment births. However, a larger number of observations and a more detailed analysis may be needed to provide a conclusive view of the relation between these two factors.

It is commonly recommended that data on business births be used in measuring and comparing entrepreneurial activities. But the number of births trends differently than the total jobs gained by the births: the number of births has risen, and the number of jobs gained has declined. If rising productivity or any other factor causes startup businesses to have a smaller initial size and lower total employment in the quarter in which they debut, the use of employment created by births as a measure of economic impact may not show the true effects of births and entrepreneurship. Because some newly born businesses will expand and become major contributors to gross job gains in subsequent quarters, the number of births may be even more significant than their initial contributions to total employment in measuring the trends of entrepreneurship and innovative activities.

As newly born businesses mature and become continuous units in employment data series, they continue to contribute to total employment—either positively or negatively, depending on the direction of their employment changes. BLS hopes to group establishments into units called cohorts, which are clusters of establishments that were born in the same period. The cohorts that survive will have a long-term impact on the job market following their initial appearance. Because of the dynamic effect of the births, one should observe changes in the number of births in a particular period in order to estimate the births' impact in the future. If a favorable economic condition leads to a surge in the number of births for a period—a "baby-boom event"—the impact will be echoed in the job market with varying intensity in the future periods. As shown in chart 3, the upward slope of the trend line for the number of births began to flatten in the end of the 1990s, thus preceding the eventual economic slowdown that began in the first quarter of 2001. An upward swing in the number of births also resumed earlier than the actual recovery of the job market that began in September 2003.

Birth and death rates

The birth rate as a percent of total active establishments was 2.9 percent for the fourth quarter of 2007, and jobs created by births accounted for .8 percent of total employment.[12] The overall birth rate as well as the birth rates by major industry sector trended downward from the third quarter of 1994 through the fourth quarter of 2007. (See chart 5.) The average quarterly birth rate for this timespan was 3.2 percent of total active establishments, .3 percent higher than the rate for the last quarter of the period. Employment resulting from births was 1.1 percent of total employment—a rather significant contribution. In the fourth quarter of 2007, jobs created by births were 11 percent of total gross job gains. This 11-percent contribution (achieved in the first quarter of operation), along with the potential to grow and become major contributors to the future expansions, make newly born businesses an important part of the data to follow and analyze. When the net of birth and death employment data is considered, the contribution of birth and death to job creation appears even more dramatic. The net of jobs created by births and jobs lost by deaths accounted for one quarter of the net job growth of 520,000 that occurred during the fourth quarter of 2006.

During the fourth quarter of 2006—the latest quarter for which establishment death data are available—195,428 establishments went permanently out of business, losing 824,354 jobs. The death rate for this quarter was 2.8 percent, and employment loss from deaths accounted for 0.7 percent of total employment. The average death rate for the 1994–2006 period was 2.9 percent of total active establishments. During the same period, average quarterly gross job losses caused by deaths were equal to 1.0 percent of total employment. Birth rates always exceeded death rates from 1994 to 2006 except for the last three quarters of 2001, the same three quarters during which the 2001 recession officially occurred. The gap between birth and death rates narrowed as the economy approached the recession period, and widened as the economy recovered. (See chart 5.) Because it takes a full year to determine whether a closure is temporary or permanent, the death data in chart 5 have a four-quarter lag. BLS will continue to publish death data with such a lag and revise closings as appropriate.

Birth and death rates exhibit a diverse pattern of change compared with rates of expansions and contractions. The contraction and expansion rates remained flat throughout the 1990s, with the expansion rate exceeding the contraction rate. The contraction rate surpassed the expansion rate near the onset of the 2001 recession and remained higher until September 2003, constituting a span of eight quarters. (See chart 6.) In contrast, the birth rate began a downward trend and the death rate began a rise in the second quarter of 1998, and the death rate exceeded the birth rate for only three recessionary quarters in 2001. The

Chart 5. Total private sector: birth rate from third quarter 1993 to fourth quarter 2007, and death rate from third quarter 1993 to fourth quarter 2006, all data seasonally adjusted
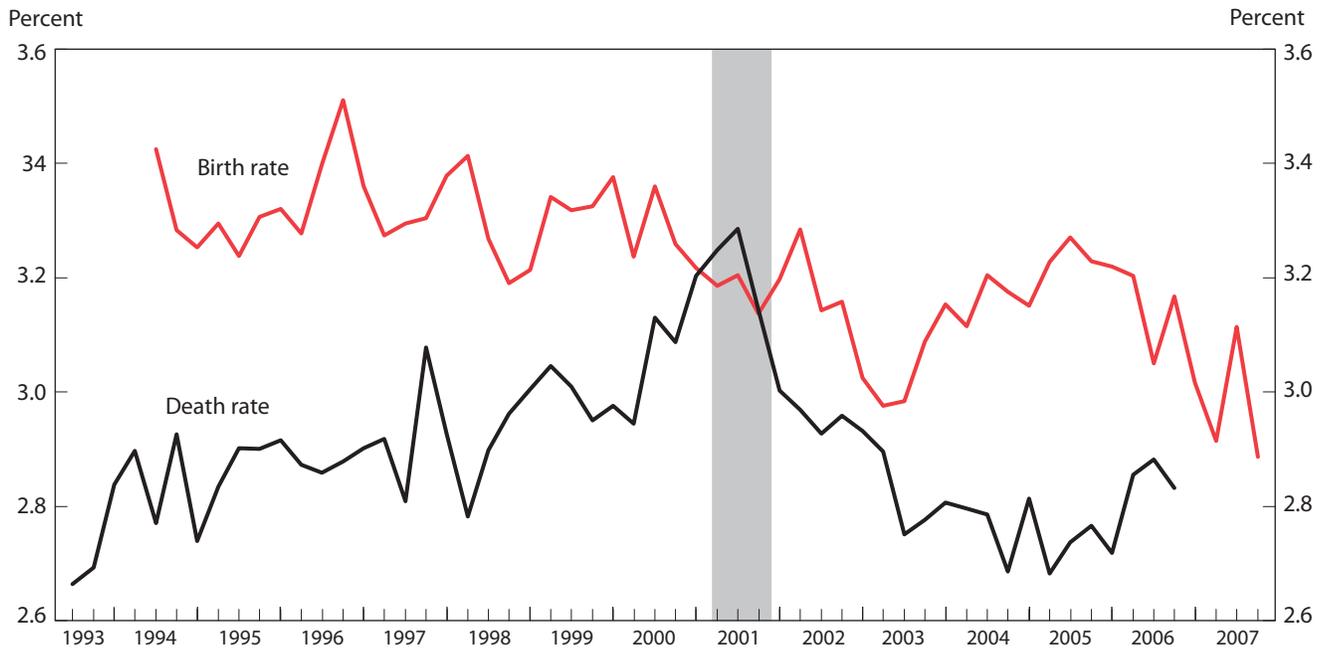

Percent   Percent

NOTE: Shaded bar denotes National Bureau of Economic Research (NBER)-designated recession (March 2001–November 2001). A birth must be preceded by four quarters of zero or no employment, and a death must be followed by four quarters of zero or no employment. Therefore, there are no birth data availble for the first year in the chart, and there are no death data available for the last year in the chart.

Chart 6. Expansions and contractions as a percent of total employment, seasonally adjusted, third quarter 1992 to fourth quarter 2007

birth rate fell to the lowest level in September 2003 and then began to increase quickly, nearing the prerecession level in December 2004 and exceeding it in June 2005. Since the fourth quarter of 2005, the birth rate seems to have started a new downward trend.

As of the fourth quarter of 2007—the most recent quarter for which relevant data are available—gross job gains from expansions had not hit the peak they had reached before the 2001 recession. The death rate fell from a high of 3.3 percent in the midst of the recession and reached an all-time low of 2.7 percent in the fourth quarter of 2004. The difference between birth and death rates indicates the rate by which the total inventory of business establishments grows. This net of birth and death rates excludes the quarterly changes in the total number of active establishments caused by temporary openings and closings of seasonal businesses. That rate is shown along with the net change in total employment in chart 7.

The sharp drop in net job growth in the middle of the 2001 recession occurred at the same time as a brief decline in the total number of active establishments. The net birth rate experienced a slight downward trend prior to the start of the recession, hit a trough in the second quarter of

2001, and has been on the rise since the official end of the recession in the fourth quarter of 2001. The net gains in total employment reached a positive level 2 years later in September 2003. The net addition to the total employers may also be seen through the gap between the birth rate and the death rate in chart 5. The gap narrowed as the economy approached the recession and widened as the economy expanded into full recovery. It appears that the trajectories of the rates of establishment births and deaths can provide additional information on the present state of the economy and help predict what may happen in future phases of the business cycle.

Entrepreneurship rate

The United States is often viewed as one of the most hospitable environment for starting businesses, but a more precise measure of entrepreneurship is needed in order to make local and international comparisons. For this purpose, one can define the concept of "entrepreneurship rate" as the number of business births per 1,000 persons in the labor force. The ratio of births to population has been used in a number of studies as a measure of entrepreneurial ac-

Chart 7. Employment growth, seasonally adjusted, third quarter 1994 to second quarter 2008; and establishment growth, seasonally adjusted, third quarter 1994 to fourth quarter 2006

NOTE: Shaded bar denotes National Bureau of Economic Research (NBER)-designated recession (March 2001–November 2001). Death rates are calculated after a lag that is longer than the period necessary for employment growth to be calculated. This causes an absense of establishment growth data for 2007 and early 2008.
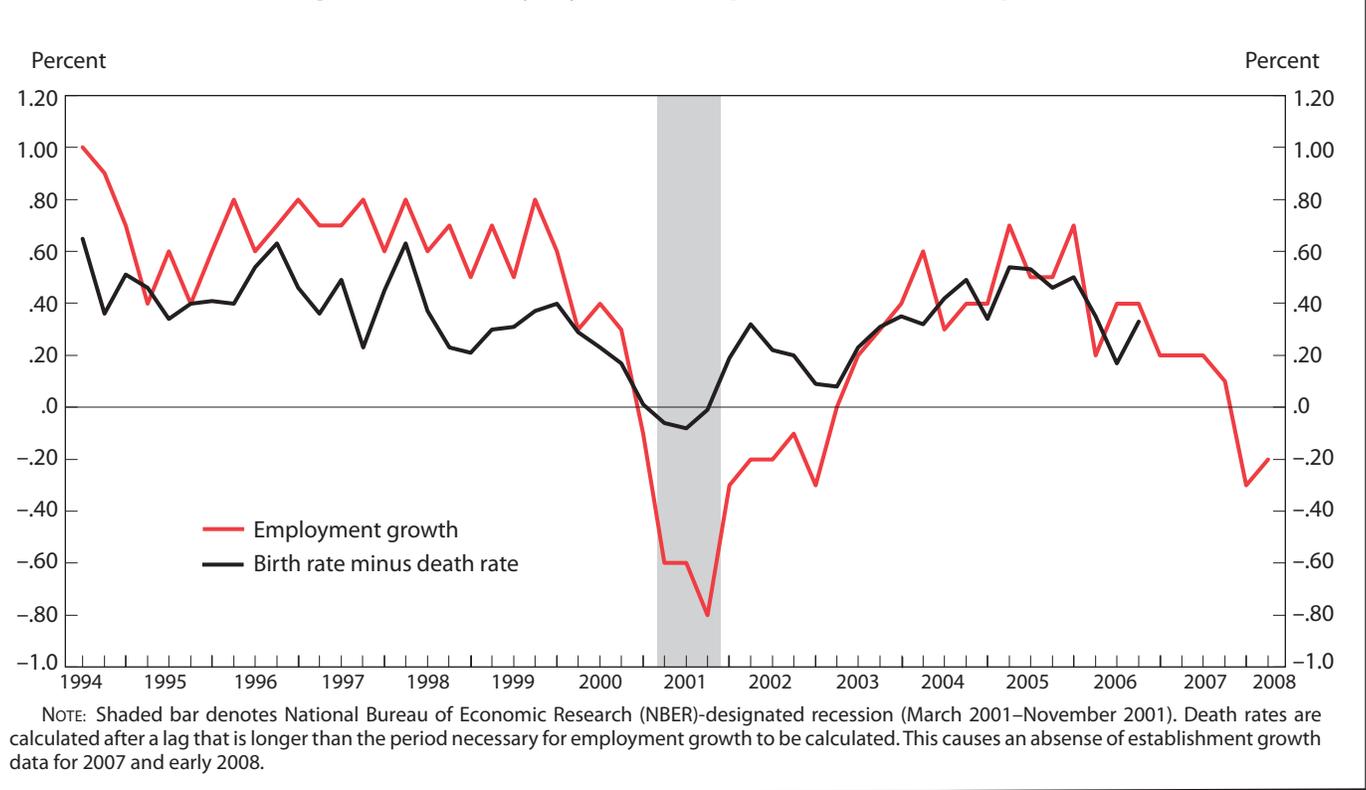

tivities for regional or international comparisons.[13] Labor force data were used to estimate this measure, taking into account births at both the firm level and the establishment level. The number of firm-level births per 1,000 persons in the labor force was 0.78 in the first quarter of 2007, up from a low of 0.75 in June 2003 but down from a high of 0.94 in the fourth quarter of 1996.

At the establishment level, the birth rate per 1,000 persons in the labor force was 1.37 in the fourth quarter of 2007, down from a high of 1.52 in the fourth quarter of 1996. The gap between the two measures reveals the share of new establishments born under the ownership of the existing firms. The birth rate per 1,000 persons in the labor force does not include "nonemployer" business entities. Nonemployers are basically self-employed people who are not included in the BED database. The birth rate per 1,000 persons in the labor force, therefore, measures entrepreneurship at the stage where startup businesses begin to hire employees. The entrepreneurship rate is an extremely valuable byproduct of birth and death data. It can not only show and compare the level and change of entrepreneurial activities across countries and regions, but can also measure the effectiveness of policies as well as the role of the number of high-paying jobs in accelerating or decelerating entrepreneurial initiatives.

Birth and death rates by industry

Birth and death rates also have been estimated and analyzed by eight selected industries: manufacturing, retail trade, information, accommodation and food, financial services, health services, education services, and construction. Birth rates have been on a downward trend across all industries. However, rates differ by industry and change at varying paces over time. Because of such variability, the ranking of industries in terms of birth and death rates changes over time. For example, the birth rate in the information sector was the highest among all industries because of the rapid development and expansion of technology in the 1990s. The rate surged from 4.0 percent in 1994 to 5.7 percent in 2000. That rate has since decreased to 2.7 percent in the fourth quarter of 2007. The birth rate in the information sector is now third highest, ranking after construction and education services. The death rate in this sector also rose—from 3.0 percent in 1994 to 5.7 percent in the third quarter of 2001. The death rate in the information sector has been declining since its peak in 2001, but it still ranks the highest among all industries' death rates.

In manufacturing, the birth rate has fallen, and it ranks

the lowest among all selected industries' birth rates. The death rate in this sector was trending upward until the end of the 2001 recession. Since then, the death rate in manufacturing has been declining, and it currently ranks the second lowest among all selected industries' death rates. Birth rates in particular sectors generally reflect the economic conditions in the sector in question. The current downturn in the construction and financial services sector is reflected in the sharp declines in birth rates in these two sectors that occurred in the first quarter of 2007.

Other definitions of birth and death

The specific definitions of birth and death chosen by BLS were the result of careful study. Economists defined five proposed measures of birth and three proposed measures of death for which they calculated time series of data from the third quarter of 1994 through the first quarter of 2007 for births, and from the third quarter of 1993 to the first quarter of 2006 for deaths. They followed two approaches. One approach is based on the first appearance of a business unit in the QCEW longitudinal database of establishments with positive employment in the third month of the quarter; the other approach is based on examining the history of each record, and this approach identifies births as records with positive employment in the current quarter preceded by zero employment in the previous four or five quarters.

Whereas the former method created one measure of birth, the latter method generated two measures, one based on analyzing employment from the third month of a quarter, and the other based on analyzing employment from all months of the quarter. The estimates generated by the second approach varied depending on the length of time during which the birth records had zero employment before reporting positive employment. To measure the effect of time, records were linked from six consecutive quarters and births were calculated on the basis of comparisons of employment from four and five consecutive third-months (henceforth, "third-month" refers to the third month of a quarter) and from 12 and 15 consecutive months; four additional measures of birth were created using these methods. The numbers of quarters that were included in the calculations were arbitrary; the primary objective in reaching back various numbers of quarters or months was to determine the amounts by which different lengths of time would change the resulting number of births. For the quarterly data, this period should exceed four quarters in order to exclude the effect of exit and re-entry of seasonal businesses. Five possible definitions of

births are summarized as follows:

- Definition 1: births are new records that appeared for the first time in the QCEW longitudinal database and have positive employment in the third month of the quarter.

- Definition 2: births are records with positive employment in the third month of a quarter and zero employment in the third months of the previous four quarters. (This is BLS's preferred definition.)

- Definition 3: births are records with positive employment in the third month of a quarter and zero employment in the third months of the previous five quarters.

- Definition 4: births are records with positive employment in the third month of a quarter and zero employment in all months of the previous four quarters.

- Definition 5: births are records with positive employment in the third month of a quarter and zero employment in all months of the last five quarters.

A death occurs when a business with positive employment reports zero employment or does not report at all for a length of time. The questions under consideration when defining deaths are similar to those under consideration when defining births as establishments with positive employment preceded by zero employment. One must decide whether employment in the third month of the quarter or employment in all 3 months of the quarter should be used, and one must also decide how many quarters or months of zero employment need to follow the positive employment in order for a death to occur. Three measures of death were calculated. Each measure is based on a particular period with zero employment following a month with positive employment reported. The relevant periods are the following:

1. four consecutive quarters in which there is zero employment in the third month,

2. five consecutive quarters in which there is zero employment in the third month, and

3. twelve consecutive months of zero employment.

The relevant length of time is the period of inactivity that is allowed before a business unit is declared dead. In the case of quarterly data, this should be at least four quarters in order to exclude seasonal businesses that have been shut down temporarily. To be symmetric, it would be preferable for the relevant timespan to be equal to the timespan applied in defining births. For these reasons, BLS's preferred meausure of death is the first one: four consecutive quarters—following a month with zero employement reported—in which there is zero employment in the third month.

Evaluation of proposed methods

To evaluate the merits of the five possible definitions of birth, one needs to examine three questions that define the differences among them. The first is whether to define a birth on the basis of the initial appearance of a record in the QCEW longitudinal database with positive third-month employment, or to define a birth on the basis of positive employment reported by a business after four or five consecutive third-months, or 12 or 15 consecutive months, of zero employment. (New records have the status of "no employment" in the previous periods.) The former definition comprises new businesses registered with positive employment for the first time, whereas the latter includes not only births but also businesses that have been inactive for more than 1 year but reported positive employment again in the current quarter. (Establishments that are reactivated within a year are considered seasonal and are counted as openings in the BED data).

Which of these two concepts is more suitable in defining a business birth? Establishment births based on the first appearance in the registry are more intuitive and logically consistent with the notion of birth as a new entity coming to life. Such a measure, however, may not be consistent with the openings in existing BED statistics and could underestimate the number of births. For example, if a business enters into the BED database for the first time with zero third-month employment, even if it has positive employment in the first and second month of the quarter, this unit will not be counted as an opening or birth. In the subsequent quarters, when the unit reports positive third-month employment, it will be counted as an opening, but not as a birth. Therefore, such a birth will never get a chance to be counted in a method based on the first appearance in the QCEW database. The sharp difference between estimates using this method and estimates using other methods indicates that using this method would underestimate the number of births.

The second question that defines the differences among the methods of counting births is the following: in the zero-to-positive employment approach, what month of employment should be used—the third month? or all months of the quarter? The third-month approach is less restrictive, and it generates the highest estimates of births

in comparison with the all-months estimates. The third-month approach is consistent with other BED data in which employment numbers from the third month of the quarter are used as the basis for job gains and job losses estimates

The third question is: how many months of zero employment need to be present before the emergence of positive employment in a record qualifies as a birth? There is no objective criterion used in selecting the length of the period of zero employment when defining a birth by the zero-to-positive-employment approach. The longer the period is, the more likely the method is to exclude reactivated businesses and to generate proper births. In data that were discussed earlier in this article, openings with third-month positive employment and zero employment in the previous four quarters were the records that were identified as births.

All methods compared

In a time series from the third quarter of 1994 through the first quarter of 2007, under five proposed definitions, chart 8 shows the number of private sector births and chart 9 shows jobs created by births. As can be seen, the pattern of change over time is similar for all definitions; in other words, the lines on each graph, although separate, move up and down almost in sync with the other lines on the same graph. Definition one, which measures birth on the basis of the first appearance of a record with positive third-month employment, generates the lowest number of births and displays a slightly different pattern of change from the other methods. Definition two has the least restriction and generates the largest number of births and employment. Definitions four and five, which define births as 12 and 15 months, respectively, of consecutive zero employment followed by positive employment, are almost identical.

Chart 10 and chart 11 show the number of establishment deaths and the number of job losses resulting from deaths—according to all three methods for estimating deaths—from the third quarter of 1993 through the first quarter of 2006. As is the case with births, the methods of estimation exhibit few differences and display the same general pattern of change over time. The number of deaths and employment losses from deaths is the highest when following the definition defined by positive employment in the third month of a quarter followed by zero employment during the third month of the four following quarters. Extending the length of time for zero employment to five quarters or observing 12 consecutive months of zero employment following reported positive employment

does not generate significant changes.

For births, definition one is rejected because it excludes a significant number of new records that appear initially with zero employment. Although definitions two, three, four, and five all generally exhibit the same trend and pattern of change with few differences, it is definition two that is selected because it is consistent with the basic BED concepts and methodology. For establishment deaths, definition one is selected. (Definition one is based on at least four quarters zero employment after the last positive employment reported.) This definition of death is somewhat unique among worldwide measures. Because the QCEW contains monthly employment, one can more easily and quickly separate seasonal closings from more permanent closings. Economists using other data sources may have to wait 2 or more years before being confident that closings are permanent. As a result, use of the QCEW-based BED measure of death will result in the most current and frequently published figures available.

These chosen measures of births and deaths have the advantage of 1. being consistent with other BED data in that they use third-month employment as a defining factor, 2. being symmetrical in dealing with both births and deaths: four quarters of zero employment before a given quarter defines birth, and four quarters of zero employment after a given quarter defines death, and 3. making births a subset of openings, which makes them consistent with the existing published BED data. The analysis of data presented earlier in this article was based on birth and death estimates derived from these selected definitions.

IN THIS ARTICLE BUSINESS BIRTHS AND DEATHS were measured using the QCEW longitudinal database. Alternative definitions were estimated and results were compared over time. The results showed small differences in the magnitude of births measured by alternative methods, but no significant differences in their patterns of change over time. The estimation of births on the basis of positive employment in the third month of a quarter and zero employment in the four previous quarters was selected as the preferred method. The same approach was employed in defining establishment deaths. Deaths are records with positive employment in the third month of a quarter followed by four consecutive quarters with zero employment during the third month. Entrepreneurial births were defined by measuring births at the firm level and excluding newly born units of multiestablishment businesses from total births.

The birth data exhibited an upward trend in the number of births, a declining trend in the total number of jobs created by births, and a downward trend in the average size of births. A decreasing average size of births was found to be likely associated with rising productivity in the U.S. economy. The number of births per 1,000 persons in the labor force has been on the rise since September 2003, following a declining trend that started in the late 1990s.

This research and analysis effort at BLS may result in routine publication of birth and death estimates. These major additions to the BED data series should prove to be useful in assessing aspects of the underlying health of the U.S. economy and in comparing U.S. employment dynamics with those of other countries.   □

[11] For the private business and private nonfarm business sectors, BLS defines the growth rate of multifactor productivity as "the growth rate of output less the growth rate of combined inputs of combined labor and capital." See **www.bls.gov/bls/glossary.htm#M** (visited Dec. 15, 2008).

[12] Birth and death rates are defined as the number of births or deaths divided by total active establishments, and active establishments are the counts of establishments with positive employment in the third month of the current quarter. To be consistent with the BED program's methodology, the number of establishments in the current quarter is averaged with the number of establishments in the previous quarter, and the resulting figure is used as the denominator in calculating the rates.

Expenditure patterns of young single adults: two recent generations compared

Differences in spending patterns for young, never-married adults in 2004–05 and their counterparts in 1984–85 may reflect differences in demographics; however, whether the changes indicate an increase or decrease in economic status remains unclear

Geoffrey Paulin

For many Americans, the age of 21 is a major point of demarcation in one's life cycle. This age marks the start of full legal adulthood—that is, the age at which the young person is no longer considered a minor and can freely engage in all legal activities, such as renting or purchasing a home. By age 21, many Americans have completed their formal education, and many more will do so during their twenties.[1] In addition, numerous individuals in this age group are starting on their first jobs leading to a career, and consequently, they face many new challenges. Achieving and maintaining financial independence can be difficult and has long-term ramifications for young adults and others in society. After all, income and spending patterns established in youth will affect one's ability not only to save for the purchase of a home, provide for a family—including future children's education—and live well in retirement, but also to contribute toward programs such as Social Security for current retirees. Clearly, then, understanding the economic status of young single adults is important for society as a whole, especially when substantial structural changes in the economy occur, as they have during the last generation.

Indeed, the changes that have taken place may lead to outcomes that differ from what has happened in the past. On the one hand, there has been a persistent belief, based on experience, that the current generation of Americans will be better off economically than the previous generation. On the other hand, since the 1990s, much literature has suggested that that belief may not be true anymore.[2] This article examines expenditure and income patterns for single, never-married young adults (persons aged 21 to 29 years) who were interviewed in 2004–05 and compares the patterns with those exhibited by single young adults 20 years earlier. The aim of the comparison is to assess the economic status of the two groups of singles in each period.

Before starting the analysis, it is important to keep in mind that many factors describe one's economic status and none by itself can provide a complete answer to the question "Who was better off when?" Each measure has its own inherent strengths and limitations that must be considered before attempting to draw conclusions.

The data

The main source of data used in this article is the Interview Survey, a component of the Consumer Expenditure Survey (CE). The CE is the most detailed source of expenditure information collected directly from households by the Federal Government. In addition, data on income and other demographics are collected. Collected periodically throughout most of the 20th century, consistent data

Geoffrey Paulin is a senior economist in the Division of Consumer Expenditure Surveys, Bureau of Labor Statistics. E-mail: paulin.geoffrey@bls.gov

from the Interview Survey are available for analysis on a quarterly basis from 1984 onward.

Participants in the Interview Survey are visited once every 3 months for five consecutive quarters. In each of these interviews, respondents are asked to report expenditures that occurred during the weeks prior to the interview. For the initial interview, the relevant period is 1 month. For the second through fifth interviews, the relevant period is 3 months. Expenditures reported in the first interview are used only for bounding purposes—that is, to ensure that respondents do not report expenditures for any item(s) in any subsequent interview(s) that they have already reported in the current interview. Only data from the second through fifth interviews are used in publication of the CE data and in the analyses conducted in this study.

The Interview Survey is conducted on an ongoing basis, with different respondents participating in different interviews during the same timeframe. That is, in any particular month, some participants are interviewed for the first time, some for the fifth. When the fifth interview is completed, the participants are dropped from the sample and replaced by new ones. In this way, about 20 percent of the sample consists of new participants each quarter. In addition, if the interviewer visits the address and finds that the original participant no longer lives there, the interviewer attempts to continue the process with the new residents at the address. For example, if the original participant completed the third interview, the interviewer asks the new participant for certain demographic and other information, but otherwise continues to ask questions normally asked in the fourth interview. In any case, each quarter of data is considered to be an independent sample, even though information from the same participants is collected in more than one quarter.[3]

Finally, participants in the survey are selected from the total U.S. civilian noninstitutional population. Participants may live in urban or rural areas and in structures such as houses, condominiums, apartments, and group quarters (for example, college dormitories). However, military personnel living on base, residents of nursing homes, and those in prisons are not included in the sample.[4]

Terms and definitions

Consumer units. The basic unit of analysis in the CE is the *consumer unit*, defined as members of a household related by blood, marriage, adoption, or some other legal arrangement; a single person living alone or sharing a household with others and who is financially independent; or two or more persons living together who share responsibility for at least 2 out of 3 major types of expenses—food, housing, and other expenses. Note that a *household* and a consumer unit are not always the same thing. A household is the physical dwelling in which a person or family resides, and it may contain many consumer units. For example, two roommates sharing an apartment may purchase their own food, pay their own half of the rent, and otherwise provide for their own expenses. They then share the same household, but are separate consumer units.

Expenditures and outlays. Technically, this article examines *outlays*, which are similar, but not identical, to *expenditures*. Both expenditures and outlays consist of the transaction costs, including taxes, of goods and services. They also include spending for gifts for persons outside the consumer unit, but exclude business purchases. However, expenditures include the full cost of each purchase, even though full payment may not have been made at the date of purchase.[5] Outlays include periodic credit or installment payments for major items already acquired, such as automobiles.[6] For example, if a consumer purchases a new automobile during the 3 months prior to the interview (that is, the "reference period"), the full cost of which is $30,000, then, under the definition of "expenditure," the consumer is taken to have spent $30,000 during the reference period. However, if the consumer financed the purchase with a loan and made payments of $500 each month of the reference period, then, under the definition of "outlays," the consumer is taken to have spent $1,500 during the reference period, plus any additional amount spent on a downpayment or a similar fee.[7] In addition, for homeowners, mortgage principal payments, if any, are excluded from the expenditure computation; for outlays, principal payments are included.[8]

Although expenditures are useful to analyze in many contexts, outlays are used in the analysis that follows because they provide a better view of monetary flows for young consumers, who presumably have less in savings or investments on which to rely for purchases and who therefore may depend on loans for financing more than do older consumers.[9]

Adjustment for expenditures for food at home. Prior to 1988, respondents to the Interview Survey were asked to report usual monthly expenditures for food at home during the reference period. Starting in 1988, respondents were asked to report usual *weekly* expenditures instead. Due to this change in the questionnaire, expenditures for food at home are not directly comparable over time. This incomparabil-

ity is evidenced by a large increase in the average for these expenditures for young single adults from 1987 to 1988 (almost 45 percent), which is inconsistent with all other year-to-year changes in these expenditures from 1984 to 2005. Therefore, prior to any analysis, 1984–85 data on food at home are adjusted to account for this change to the extent possible. Outlays that include food at home as a component, either directly (for example, total food outlays) or indirectly (for example, outlays for all other items, which are computed by subtracting several expenditures from total outlays), are recomputed with the use of the adjusted expenditures for food at home. (Details concerning the change in the questionnaire and the computation of the adjustment factor are given in "Adjusting expenditures for food at home," in the appendix, pp. 40–43.)

Group of interest: young single adults. In this article, the main analysis is performed using data from young, single, never-married adults aged 21 to 29 years who constitute their own consumer units.[10] The group is limited to single-member consumer units in order to facilitate comparisons across time. For example, if all consumer units that include at least one 21- to 29-year-old are compared, changes in patterns may be due solely to changes in the composition of these units: if there are more (or fewer) married couples, single parents, or other non-single-member units in the later period, expenditure patterns for the group as a whole will appear to differ, even if there has been no change when only married couples, single parents, or other non-single-member units are compared. In addition, the sample is limited to never-married singles because singles who were previously married may have very different expenditure or other patterns based on differences in their life experiences or differences in income resulting from their unions. These patterns may even include expenditures for a child who lives in a consumer unit different from that of the previously married parent. Therefore, to remove the potential influence of these factors on the analysis, only never-married singles are included, wherever possible.

Quarterly outlays or annualized outlays? In the Interview Survey, data for expenditures and outlays are collected quarterly in most cases. That is, respondents are usually asked to report values for expenditures or outlays that occurred during the 3 months prior to the interview. For convenience, the data for expenditures and outlays presented in this article are annualized prior to analysis. That is, quarterly values are multiplied by 4. However, the annualized values do not represent calendar-year spending. For example, respondents interviewed in January 1984 reported outlays that occurred between October and December 1983. Similarly, respondents interviewed in February 1984 reported outlays that occurred between November 1983 and January 1984, thus crossing years. Also, multiplying an individual's quarterly outlays by 4 may not accurately represent what that individual actually spent during the 12-month period of interest. However, on average, this approach provides a reasonable estimate of outlays for a 12-month period.

Real dollars or nominal dollars? In performing economic comparisons across time, it is essential to control for changes in prices, because changing prices affect purchasing power. That is, if a person spent $1 for apples yesterday, but $2 today, then the person did not buy more apples today if the price of apples doubled since yesterday. Price indexes are often used to convert *nominal* (that is, reported) dollars into *real* (that is, price-adjusted) dollars, either by converting yesterday's expenditures into today's dollars or by converting today's expenditures into yesterday's dollars. (For more information on this topic, see "Real or nominal expenditures?" in the appendix, pp. 39–40.)

Sample or population? In conducting the CE, it is impossible to interview every consumer unit in the United States (*the population*). Therefore, a representative group is interviewed. The members of this group constitute the *sample*. To obtain population estimates, each consumer unit in the sample is weighted by the number of consumer units it represents. In 1984–85, there were 2,359 consumer units of interest sampled; as shown in table 1, together they are estimated to represent nearly 4.9 million consumer units in the population. In 2004–05, there were 2,158 consumer units of interest sampled, representing about 4.6 million consumer units in the population.[11]

Statistical significance. Because data compared across groups come from samples of each group, rather than entire populations, it is important to consider the probability that differences in outcomes are the result of actual differences in the population and not due to chance. Depending on the type of sampling performed, different formulas are available to compute the *statistical significance* of the outcome—that is, the probability that the difference was due to chance alone, rather than being a real difference in outcomes. In the analysis that follows, when results are described as "statistically significant," the outcome is not likely to have been due to chance alone. (Tests used to measure statistical significance are described in "Measuring statistical significance: types and computations of *t*-statistics," in the appendix, pp. 43–44.)

Table 1.	Demographic characteristics of never-married young adults (aged 21 to 29 years), 1984–85 and 2004–05		
[In percent]			
Characteristic		**1984–85**	**2004–05**
Estimated population (rounded)...........		4,854,000	4,610,000
Percent distribution			
Educational status:			
Highest level attained:			
High school diploma or less		26.2	17.8
College experience...........................		73.8	82.2
Attended college		[1]40.1	[2]45.3
Graduated college........................		[3]33.7	[4]36.9
Currently enrolled in college:			
Full time..		25.6	35.7
Part time..		7.0	7.4
Not at all.......................................		64.7	53.4
Not eligible[5]		2.7	3.5
Housing tenure:			
Homeowner..		8.0	15.8
Renter		92.0	84.2
Race and ethnic origin:			
Hispanic		3.5	7.1
Non-Hispanic		96.5	92.9
Black...		8.3	10.1
White and other		88.2	82.8
Men		57.6	59.3
Women..		42.4	40.7
Size of dwelling:			
Homeowners...			
Rooms, other than bathrooms........		5.0	5.3
Bedrooms...		2.4	2.5
Bathrooms..		1.2	1.5
Half baths..		.2	.2
Renters:			
Rooms, other than bathrooms		4.1	4.2
Bedrooms...		1.8	2.1
Bathrooms..		1.2	1.3
Half baths		.1	.1

[1] Includes those who report attending or completing 1 to 3 years of college and those who report attending, but not completing, 4 years of college.
[2] Includes those who report some college, but no degree, and those who report receiving an associate's degree (occupational/vocational or academic).
[3] Includes those who report completing 4 years of college or attending graduate school.
[4] Includes those who report receiving a bachelor's degree, master's degree, professional school degree, or doctoral degree.
[5] Did not garaduate high school.

Limitations of the data

A complete description of economic well-being includes measures that are not available in the data analyzed. For example, the CE does not collect information about expectations of the future. Presumably, the anticipation of a particular event or outcome in the future influences expenditure patterns in the present. For example, if one expects to make a major purchase (for instance, a home or a car) soon, one may save more in the present than someone who does not expect to do so for some time; or, as discussed subsequently, the more one expects to earn in the future as the result of obtaining a college degree, the more one is willing to pay for it. As another example, rapid changes in technology, such as those which occurred during the period under study, presumably have ramifications for economic well-being that are impossible to measure by examining expenditures alone.[12]

In addition, a consideration of assets and liabilities is excluded from this analysis. Although the CE collects information on assets and liabilities, the information is not detailed enough for purposes of analysis. For example, some information about levels of debt and to whom it is owed is collected; however, information about many sources of debt, including school loans, is not collected separately from information about other debt.[13] Furthermore, the CE data on assets and liabilities are not considered as reliable as expenditure data, due to nonresponse.[14] Finally, unlike expenditure data, which are collected during each interview, data on assets and liabilities are collected only during the fifth interview. Therefore, not all consumer units that are interviewed have an opportunity to provide information about assets and liabilities.[15] Despite these data limitations, young singles presumably make expenditure decisions with the preceding factors in mind. Consequently, those factors are implicitly included in the analysis that follows.

Demographic analysis

Before comparing groups, it is important to understand their basic demographic characteristics. Changes in demographics, such as educational attainment, may explain differences in economic attainment. For example, a higher percentage attending college may indicate a better trained workforce whose members are more able to enter professional or skilled careers. At the same time, changes in demographics may be associated with changes in tastes and preferences that would change expenditure patterns.

Population share. The data indicate that, despite growth in the U.S. civilian noninstitutional population, the number of young adults (of any marital status, living alone or with others) in that population has decreased over time.

For example, the number of consumer units in the U.S. population increased from more than 90.5 million in 1984–85 to more than 116.6 million in 2004–05. At the same time, the approximate number of 21- to 29-year-olds who lived in consumer units of any size decreased from 37.5 million in 1984–85 to 34.3 million in 2004–05. As a result, the number of consumer units reporting at least one member between the ages of 21 and 29 fell from nearly 27.7 million (almost 31 percent) to 25.7 million (22 percent).

Nevertheless, despite the overall decrease in the number of young adults over this time span, the estimated number of young *single* (never-married) adults increased from about 17.2 million to 20.3 million. In addition, the number of consumer units that included at least one young single increased from 14.5 million to 16.7 million, and the values increased dramatically for consumer units with at least one young adult of *any* marital status. For example, in 1984–85, more than half (53 percent) of these consumer units included at least one young *single* adult, with an average of 0.6 per consumer unit. In 2004–05, nearly two-thirds (65 percent) included at least one young single adult, with an average of nearly 0.8 per consumer unit.

Presumably, these findings indicate that although, due to demographic shifts, there were fewer young adults in the population, they were marrying later in life in 2004–05 than they were in 1984–85.[16] If so, whether this trend indicates an improvement or a deterioration in that age group's economic status is not clear. On the one hand, the decision to wait may reflect the desire to complete a degree or establish a career before undertaking such an important commitment as marriage. On the other hand, it may be that young persons still want to marry early, but find it too difficult financially. At any rate, as evidenced by this discussion, the trend toward later marriage again underscores the importance of narrowing the subject of study to young singles. Attempting to include marriage, and even children, into the analysis introduces comparisons that are too complex to complete meaningfully.

Education. According to table 1, in 2004–05 young singles reported higher levels of educational attainment than they did in 1984–85.[17] From the earlier survey period to the later one, the percentage reporting a high school diploma or less dropped substantially (from 26 percent to 18 percent), while the percentage reporting at least some college experience increased notably (from 74 percent to 82 percent).[18] In addition, those enrolled in college full time increased their share from a little more than 1 in 4

(26 percent) to well over 1 in 3 (36 percent).[19]

Higher education is usually considered to be a benefit, leading to higher pay for professional or skilled workers. This is especially true as changes in technology and communications during the intervening years have created jobs, such as computer technicians and administrators, that may require at least some college education for a job-seeker to qualify for employment. However, at the same time, the Consumer Price Index (CPI), which measures changes in prices for goods and services that urban U.S. consumers purchase, shows that the cost of college tuition and fees more than quadrupled—rising 365.3 percent—from January 1984 to December 2005.[20] This increase is in contrast to one of 93.1 percent—less than double—for *all* goods and services over the same period. Thus, young singles in the later period may have been receiving education in larger numbers, but they were facing considerably higher prices than their historical counterparts. In order to benefit from their education, at least in a purely financial way, expected wages and salaries or other income would have to rise substantially to compensate for the increased cost of education.

Housing status. In recent years, there has been much discussion regarding students moving back into their parents' homes after college, rather than into their own dwellings. Many reasons for this development have been posited, and some would suggest that it is due to a decrease in economic well-being—for example, because nowadays students are unable to afford housing on their own. However, others suggest that moving back with parents is a benefit to young adults, as it allows them to forego rent and spend savings therefrom on consumer goods.[21] It could also be that young adults who choose to live with parents do so in order to save for a downpayment on a nicer home than they could have afforded if they had to pay housing expenses while saving.

Whatever the case, the CE data do not support this conclusion. To demonstrate, the sample is expanded to include all consumer units consisting of *at least* one never-married adult aged 21 to 29 years. Expanding the sample to take these individuals into account ensures that young singles who live with their parents, as well as those who live with others but who do not pay rent or are otherwise not financially independent, are included in the analysis. In this new sample, 35 percent of young singles were reported to be the child of the reference person[22] in 2004–05, compared with 48 percent in 1984–85. In addition, the percentage reporting that they were the reference person increased from 39 percent in 1984–85 to 43 percent in 2004–05.[23]

Another key factor in considering well-being is that, despite a sharp increase in home prices in many U.S. cities in recent years, young single adults in 2004–05 were more likely to own their homes than they were in 1984–85. The percentage of young single homeowners doubled from 8 percent to 16 percent during that time. Usually, home-ownership is considered to indicate higher economic status than renting. Owning a home provides the purchaser with not only living quarters, but a valuable asset against which to borrow in case of emergency. Of course, if young adults in the later period were buying homes with riskier, more exotic mortgages that were not available in the earlier period, that could have led to worse outcomes than renting. However, the answer to that question is beyond the scope of the CE data.

Economic analysis

Macroeconomic factors. One indicator of economic conditions is the real value of *gross domestic product* (*GDP*). GDP measures the value of all goods and services produced in an economy.[24] According to this measure, both groups look like they were about equally well off. Each group lived and worked during a period of economic growth. Real GDP expanded both from 1983 to 1985 (by 11.6 percent) and from 2003 to 2005 (by 6.8 percent).[25] Interestingly, the two groups also grew up in similar historical contexts as far as economic growth is concerned. In this regard, real GDP grew at an average annual rate of about 3.3 percent from 1964–65 to 1984–85 and 3.0 percent from 1984–85 to 2004–05,[26] while the population grew at an average annual rate of about 1 percent over each of the two periods.[27] Therefore, each group experienced periods in which real GDP grew faster than population growth, indicating that there were more goods and services per person available to be consumed or otherwise used in the economy.

Though important, the GDP values reflect changes for the economy as a whole—not necessarily for the group of interest. Therefore, other macroeconomic indicators also are useful to examine. One of these is the *unemployment rate*. This measure describes the ratio of persons actively seeking work, but unable to find it, to all persons in the labor force, which includes the former group as well as those who currently hold jobs.[28] Although the available measures are not precise or specific to the group in question, there are historical data readily available to describe outcomes.[29] Using such data enables rates for young (never-married) singles to be computed for those aged 20 to 24 years. Data also are available for adults aged 25 to 29 years, but no data are available for never-married persons

in that age group.

Both sets of data show a decline of nearly 2 percentage points in unemployment rates for young adults in each age group. Although they experienced higher rates of unemployment than the general population (all adults aged 20 years and older) did in each period (about 6.5 percent in 1984–85 and 4.7 percent in 2004–05), the decline in rates for young adults indicates that they were better off in the later period than the earlier one.[30] The following tabulation shows unemployment rates for young singles and for all young adults for 1984–85 and 2004–05:

Category	Young singles only (20 to 24 years)		All young adults aged 25 to 29 years	
	1984–85	2004–05	1984–85	2004–05
Total	11.7	9.6	7.8	6.0
Men..............	12.8	10.6	7.6	5.8
Women	10.2	8.3	8.0	6.2

In addition to these unemployment figures, certain related macroeconomic factors may have affected economic well-being differently for young adults in the two periods. If so, these factors also support the hypothesis that young adults were better off in the second period. For example, the first group experienced several serious economic recessions from the mid-1970s to the early 1980s that were marked by historically high levels of unemployment. By contrast, there were only two recessions from 1984–85 to 2004–05 (in 1990–91 and 2001), each with peak unemployment rates lower than in the earlier downturns.[31] Although 1984–85 and 2004–05 were each periods of growth in real GDP, the differences in economic outcomes in the preceding years may have affected the abilities of the young adults to secure jobs or savings prior to the years of study or may have affected the finances of those on whom they would normally rely for support, such as parents or other family members.[32] These experiences also may have affected the group's expectations about the future and therefore affected its members' planning.

Microeconomic factors: measures using outlays. In defining the economic status of a particular group, many persons would probably immediately think of income as the appropriate measure. However, outlays are used in this article, for both theoretical and practical reasons.

From a theoretical viewpoint, total outlays reflect not only income received today (that is, current income), but expectations of future income. For example, an applicant seeking a student loan almost certainly knows that his or

her current savings and income are inadequate to cover tuition, but has the expectation that future earnings (enhanced by the degree sought) will more than repay the loan. The sum of current income and expected future income is known as *permanent income*; the idea that consumers spend money on the basis of their permanent income levels is known as the "permanent-income hypothesis."[33] Because outlays are hypothesized to be based on permanent income, they are used as a proxy thereof in this analysis.

Among the practical reasons for using outlays rather than (current) income with CE data is that, prior to 2004, income before taxes was published only for "complete income reporters." In general, complete reporters were those for whom at least one member of the consumer unit (usually the reference person) reported a value for a major source of income, such as wages and salaries. However, even complete income reporters did not necessarily provide a full accounting of income from all sources. For example, the respondent might have provided a value for wage and salary income, but not known or refused to provide the value for interest income. Relying on complete reporters only, then, reduced available information in two ways: Not all respondents were complete reporters, and not all complete reporters provided full income information for analysis. Using total outlays as a proxy for permanent income solves both problems, because values for outlays are either reported or, where appropriate, estimated by various methods.[34]

Using outlays to assess economic status. Perhaps the first answer to come to mind to the question, "Which group is economically better off?" is the answer to another question: "Which group has more income?" As has already been demonstrated, even answering this question is not as straightforward as it might seem. A simple comparison of permanent incomes would make it seem as if the young adults in 2004–05 were better off than those in 1984–85: total annualized outlays for the average young single adult studied rose from $13,145 to $22,744 over the period between the two surveys, an increase of 73 percent! However, in the United States, total annualized outlays probably would be observed to increase during *any* 20-year period since World War II, simply because of inflation, which is defined as a rise in prices for goods and services when other factors (such as size and quality) remain essentially constant. Given this situation, it is more accurate to compare *real* outlays (those adjusted for price change with the use of the CPI for all goods and services) than *nominal* outlays (unadjusted figures, as cited earlier). The

2-year average of the annual CPI for all goods and services rose nearly 82 percent from its base in 1984–85 (105.8) to its value in 2004–05 (192.1). That means that the $13,145 spent in 1984–85 would purchase about the same amount of goods and services as would $23,867 in 2004–05. By this measure, young adults in 2004–05 were *worse* off than their earlier counterparts, experiencing a decrease of almost 5 percent ($23,867, compared with $22,744) in their real outlays. However, caution must be used in interpreting this finding, because the difference in means is not statistically significant.

Of course, the preceding finding relies on certain assumptions, namely, that the same goods and services are purchased in each year by each group, that qualities remain unchanged, and so forth. Even so, by this measure, young adults in the later period appear to be worse off than they were in the earlier period. But perhaps the same is true of all other consumers. If so, is the decrease in purchasing power experienced by young singles larger, smaller, or about the same as that experienced by others? In other words, how are young adults faring compared with the rest of the population?

Comparing the changes in real total outlays from 1984–85 to 2004–05 for young singles with those of other single, never-married adults who also were surveyed during those periods is one way to attempt to answer this question. Before proceeding, however, it is useful to remove outlays for food at home from both groups, because of the change in questionnaire occurring in 1988. As noted earlier, young, single, never-married adults exhibit a large change (almost 45 percent) in food-at-home expenditures from 1987 to 1988 that is inconsistent with annual changes in these expenditures for this group in other years. Other single, never-married adults exhibit a similarly large (more than 38 percent) and inconsistent change in these expenditures. However, the factors required to adjust their expenditures are almost certainly different from those required for young single adults. Performing this adjustment would therefore add one more element of uncertainty to the comparison: if differences are found in the rates of change of total outlays for these groups, how much will be due to actual differences in expenditure patterns and how much to qualitative differences in the estimated factor for adjustment of food-at-home expenditures for each group? Therefore, for simplicity, outlays less food at home are compared.

For young singles, real total outlays less food at home fell 3.8 percent over time, from $21,613 in 1984–85 to $20,795 in 2004–05. For other singles, real total outlays less food at home increased 6.1 over the same

period, from $24,415 to $25,906. Although this finding appears to indicate that young singles are falling behind in permanent income while others are gaining, it is not conclusive. First, neither change is statistically significant, indicating that the differences in means observed for each group across time may be due to chance alone. Second, the increase in outlays for other singles may be due to changing demographics within this group. For example, the proportion of singles aged 35 to 54 years increased from 39 percent in 1984–85 to 56 percent in 2004–05. In each year during the period examined, never-married adults in both age groups had the highest levels of average total outlays. Therefore, even if average real total outlays for singles aged 35 to 54 years have not changed over time, the fact that there are more members of that group in the sample will increase the mean for the entire sample of other singles.

Using shares to measure outcomes

Another useful tool for comparing the economic well-being of different groups is derived from a finding known as *Engel's proposition*. In 1857, Prussian economist Ernst Engel reported that, as income increases, the share of total expenditures allocated to food decreases.[35] The assumption in the analysis presented in this article is that the smaller the share of total expenditures a consumer allocates to expenditures for basic needs such as food, the larger is the share available to allocate to other items. Therefore, understanding the allocation of shares of total outlays provides insight into the economic well-being of the groups studied. (For more information on analyzing shares, including caveats associated with this type of analysis, see "Analyzing shares," in the appendix, pp. 38–39.) Table 2 shows shares of total outlays that young adults allocated to selected goods and services in 1984–85 and 2004–05.

Several findings are of note. First, the share of outlays allocated to food has declined over time—by more than 2 percentage points, in fact. Taken alone, this may indicate an increase in economic well-being. However, food outlays can be decomposed into two parts: outlays for food at home (for example, food purchased at grocery stores) and outlays for food away from home (for instance, food purchased at restaurants). Analyzing these components separately is useful, because they represent two different types of spending. Because of the convenience, change in ambience, and typically higher cost associated with meals at restaurants, these meals are considered to be a treat for many consumers; therefore, it is reasonable to suppose that an increased share for food away from home indicates an

increase in well-being, while an increased share for food at home indicates a decrease in well-being. Over the period examined, the shares for food at home *and* for food away from home both decreased. Each of these changes is statistically significant, as are many of the other changes in share shown in the table. However, the directions of the changes in the components of food spending are contradictory, one indicating an increase, and the other a decrease, in economic well-being. Resolving this apparently paradoxical outcome is the topic of the next section. (See also "Analyzing shares," in the appendix, pp. 38–39, especially p. 39.)

Other measures using outlays

Although analyzing shares of outlays provides an easy, intuitive way to compare economic statuses, it has its limitations. In historical comparisons, one major limitation is, once again, price change. When outlays within a certain period are compared, it is usually assumed that all groups face roughly the same prices. However, across different periods, prices for some goods and services may have risen, perhaps rapidly, while others stayed the same or even dropped. When prices are not changing at a uniform rate, the shares can be affected in ways that do not accurately reflect the underlying idea of analysis using a framework based on Engel's proposition. (See "Analyzing shares," in the appendix, pp. 38–39.) Therefore, comparing real (price-adjusted), rather than nominal (contemporaneous), outlays for specific items is a useful way of seeing whether a decrease in share is due to less consumption or a change in prices.

The CPI for food at home rose more than 81 percent from 1984–85 (103.6) to 2004–05 (188.0). Therefore, the real-dollar expenditure for food at home in 1984–85 was about $2,252, which is more than the $1,950 spent in 2004–05. Similarly, the CPI for food away from home rose about 79 percent from 1984–85 (106.3) to 2004–05 (190.5). Therefore, the real-dollar expenditure for food away from home in 1984–85 was about $1,437, which is more than the $1,073 spent in 2004–05. In each case, the real-dollar expenditure in 1984–85 is statistically significantly different from the value observed in 2004–05. Consequently, these findings are consistent with the Engel analysis, which indicates a higher economic well-being in the second period than in the first due to a decrease in expenditures for food at home, but a lower economic well-being in the second period due to a decrease in expenditures for food away from home.

Further analysis reveals another interesting finding: Although the percentage of respondents reporting expenditures for food at home remained unchanged (almost 97

Table 2. Average annualized outlays and shares, young single adults, 1984–85 and 2004–05

Outlay category	Average annualized outlay			Share (percent)		
	1984–85		2004–05			
	Nominal dollars	Real 2004–05 dollars	Nominal/real dollars	1984–85	2004–05	*t*-statistic
Total outlays[1]	$13,145	$23,866	$22,744	100.0	100.0	…

All other outlays[1]	2,699	4,900	4,186	20.5	18.4	[2]–2.45

[1] Item or subcomponent computed with the use of adjusted values for food at home in 1984–85; see "Adjusting expenditures for food at home," in the appendix, pp. 40–43.

[2] Indicates statistically significant difference in shares when periods are compared.

NOTE: To convert to real 2004–05 dollars, nominal 1984–85 dollars are multiplied by 192.1 (the average CPI for 2004–05) and divided by 105.8 (the average CPI for 1984–85). Components may not add to aggregate values

percent in each period), the percentage reporting expenditures for food away from home fell nearly 5 percentage points (from 90.8 percent to 86.3 percent). This finding supports a diminution in economic well-being, given the smaller percentage of young singles who report expenditures for food away from home.

However supportive, by themselves these numbers do not conclusively indicate that the second group was worse off than the first. For example, an increased variety of frozen and prepared foods in the second period may mean that consumers can enjoy, at home, the convenience of food away from home at lower, grocery store prices. In addition, the consumer can make one trip to the grocery store each week and purchase all meals at once, rather than visiting a fast-food establishment every day, thus saving time. If all this is true, then the decreased share for food away from

home may indicate an *increase* in well-being. Yet, if it is true, it is inconsistent with the fact that real expenditures for food at home fell between the two periods; that is, given that the price index for food at home rose between the two periods, purchasing more food at home and less food away from home should lead to *higher*, not lower, real-dollar expenditures for food at home in the second period. Still, this outcome is not implausible. The price index for food at home is based on what *all* consumers purchase, and not solely on what young singles purchase. If young singles are purchasing more food at home, and the prices of the foods they tend to purchase have increased less than the prices of other types of food at home, then the preceding findings are consistent with the hypothesis described here (that is, that young singles are substituting lower priced foods from grocery or other stores for food

from restaurants). In fact, the CPI for frozen and freeze-dried prepared foods increased less than 48 percent (from 103.8 to 153.2) from January 1984 to December 2005, substantially less than the 81-percent increase in prices already reported for food at home in general.[36] However, to investigate this hypothesis fully requires both further investigation into price increases for specific foods and an examination of data from the CE's Diary component, or Diary Survey, which, unlike the Interview Survey, is designed to collect detailed information on food expenditures. Such an investigation, while interesting for future work, is beyond the scope of this study.

Regardless, expenditures on other goods and services also are useful to examine. First, consider the case of shelter and utilities.[37] The share allocated to these outlays has increased substantially, from less than one-fourth to nearly one-third of total outlays. Again, it is possible that housing attributes account for this change. Now, if outlays for shelter and utilities have risen because young singles are purchasing or renting larger homes, the change in share may be due to an increase in their well-being. However, evidence to suggest such purchases is limited. For example, only the increase in number of bathrooms (see table 1) is statistically significant for both owners and renters. The changes in the numbers of bedrooms and half baths for renters, while statistically significant, are not necessarily economically significant. (For example, the number of bedrooms for those who rent increased from about 1.8 to about 2.1.) Neither homeowners nor renters experienced a statistically significant change in "rooms, other than bathrooms." Although other factors, not measured in the CE, also affect these outlays—for example, the quality of the neighborhood in which the housing exists—the substantial change in these shares, coupled with the considerable increase in housing prices noted in recent years, may be evidence of a diminution of well-being for this group, or at least that the increase in well-being from slightly larger dwellings is more than offset by the increase in outlays. However, these data do not tell the full story. The numbers of rooms, bedrooms, bathrooms, and half baths are all described for the *consumer unit*, yet many of the consumer units sampled actually reside in the same *household*. It is quite possible that numbers of rooms per consumer unit have not changed, but that the number of households in which these consumer units reside has changed; if the number has increased, it could indicate an increase in well-being. To illustrate, consider two young singles sharing a one-bedroom apartment (that is, two separate consumer units sharing one household). Suppose that each roommate is interviewed and reports that the

apartment has one bedroom. Then the data would show two separate consumer units, each with one bedroom. Now suppose that one roommate moves into a new apartment, also containing one bedroom. Then, assuming that each of the former roommates still lives alone, the data still show two separate consumer units with one bedroom. Yet, if they prefer to live alone, the constant number of rooms per consumer unit would not reflect the hypothetical increase in their well-being. Fortunately, the data provide information that allows the analyst to distinguish these two cases. That is, it is possible to count the number of consumer units per household to see whether two roommates are sharing one household with one bedroom or two young singles live alone in separate households, each of which contains one bedroom. Analyzed in this way, the results tell a different story: first, in 1984–85, more than one-third (nearly 36 percent) of the young singles studied lived in a household with at least one other person;[38] then, in 2004–05, less than one-fourth (under 23 percent) did. (See table 3.)

Of course, some caution must be used in interpreting these numbers. The data are not edited for consistency, for example. Therefore, it is possible that, due to differences in the way respondents interpret their situations (for instance, one housemate reports the second bedroom, which is being used as a den, as a room other than a bedroom, while the other reports it as a second bedroom), data entry error, or another reason, different numbers of rooms or bedrooms are reported for the same household within or across interviews. Also, some of the information is missing due to nonresponse or some other reason. But assuming that these factors are random each year, the data obtained provide useful information to help measure changes in numbers of rooms available to young single adults. Analyzed in this way, the data show that, regardless of household composition—at least, whether one or more than one person lives in the household—the number of rooms per capita has increased over time. Although the increases are small, they are statistically significant in most cases. Especially because more young singles are the sole occupants of their households, it is more difficult to argue that the increased expenditures for housing noted at the consumer-unit level clearly indicate a diminution of well-being. Those who are the sole occupants of their households may value privacy enough to pay the extra dollars, and if they can afford to do so in larger numbers in the later period than in the earlier period, then they are arguably better off in the later period, or at least any diminution in well-being due to higher housing prices is offset at least partially by an increase in privacy or in the

Housing attributes of young singles, households including at least one young single person, 1984–85 and 2004–05

Characteristic	Household includes only young single person			Household includes at least one other person

[1] Based on test of proportions, where percentages are compared, and difference in means, where number of rooms are compared. (See "Measuring statistical significance: types and computations of *t*-statistics," in the appendix, pp. 43–44 (especially p. 44), for details.)

[2] Results are not computed for multiple-member households. The problem is that, within the household, there can be a mix of owners and renters. For example, the homeowner may rent a room or part of the house to at least one young single person. In addition, in this case the consumer unit that owns the home may be of any composition. That is, the owner may be a young, single person, as defined throughout this study, or may be of a different age or marital status.

[3] These households include at least one young single person as defined in this study who constitutes a unique consumer unit within the house-hold. However, the remaining members may constitute any number of consumer units from one to the number of other members of the house-hold. For example, if a husband and wife with two children rent a room to a young single, the household size is five, but the number of consumer units is two. In this case, the per-capita number of rooms is still computed to be the number of rooms in the household divided by the household size, whether or not the renter has full use of other rooms in the house.

[4] Less than .05.

NOTE: Values presented are for the sample and are not weighted to reflect the population. Weights computed in the survey are designed for use with consumer units, not households.

number of bedrooms and bathrooms per capita.

In contrast to housing expenditures, which are necessary for at least a minimal level of economic well-being, travel expenditures are purely discretionary for most consumers. Therefore, an increase in the frequency of purchasing goods or services related to travel or in dollars allocated toward trips presumably indicates an increase in economic well-being. However, for young singles, the share of total outlays allocated to travel has fallen substantially, from 5 percent to 3 percent. At the same time, the percentage of respondents reporting travel expenditures has decreased sharply, from more than half (53 percent) to more than one-third (35 percent). The percentage reporting many of the components of travel expenditures (such as food, lodging, transportation, and entertainment on trips) also has declined. Therefore, the drop in share is not the result of decreased prices, nor is it likely that members of this group are making different lodging arrangements than before (for example, staying with friends or relatives instead of in hotels). Young singles simply appear to be traveling less. However, they are not unique in this regard: The percentage reporting travel expenditures (including the components previously described) has decreased for all other consumer units as well during the period exam-ined. (See chart 1.) Accordingly, rather than decreased prices, *increased* prices may play a role.[39] In addition, these changes in travel expenditures may be explicable by changes in technology. For example, the percentage reporting travel expenditures decreased as e-mail, cellular telephones, and instant messaging became more available. Therefore, consumers in general (and young singles specifically) may be substituting new forms of communication for travel, which would indicate an increase in their economic well-being. That is, young singles in the later period enjoy choices not available to those in the earlier period.[40] However, there is still no perfect substitute for the personal visit. From this perspective, the availability of new technology mitigates the decrease in well-being resulting from less frequent travel, whatever its cause (for example, increased prices), but does not necessarily negate (or outweigh) the decrease entirely.

Of particular interest is the change in shares for educational expenses, which nearly doubled over the period examined. This change is challenging to interpret. The proportion of young single adults enrolled in college full time rose sharply—from just above one-fourth (26 percent) to more than one-third (36 percent); the proportion of part-time students remained unchanged at about

Chart 1.   Percent reporting expenditures for travel, 1984–2005
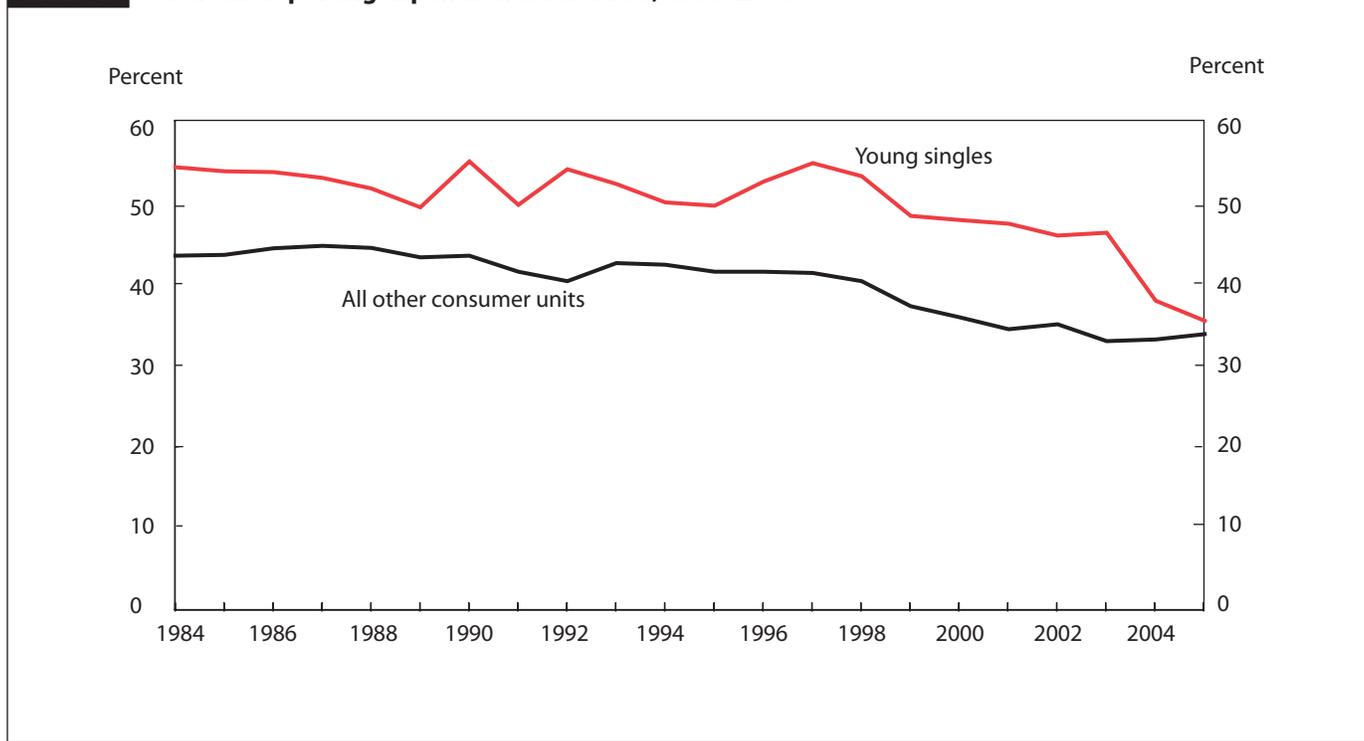

Percent

Percent

7 percent, while the proportion not enrolled (including those not eligible) declined almost 11 percentage points. (See table 1.) However, those reporting educational expenditures actually dropped slightly—from 26 percent to 24 percent. Of course, not all of the expenditures included in the CE definition of educational expenditures are for college tuition; however, the tuition expenditure accounts for a substantial portion.[41] Although many of these students may be receiving scholarships, participating in deferred payment plans, or working for payment of tuition instead of working for other pay, or may be children of parents who pay their tuition directly to the school, it is likely that those who do make payments were paying much more for their education in 2004–05 than those who did in 1984–85, even after adjustment for general price changes. In support of this claim, recall the increase in college tuition and fees described earlier. The fact that more young adults are attending college either because of a greater opportunity to do so or because of the changing nature of the general economy probably reflects an improvement in economic well-being. However, the fact that the price of going to college has escalated so much means that the expected gains from a college education would have to rise substantially for current students to "break even" with their older counterparts.[42]

Demographic differences among young singles

So far, the analyses presented have focused on young single adults as a group. However, as noted earlier, there are demographic differences within this segment of the population that either may account for changes in the group overall or may be obscured when the group is examined as a whole. For example, an increase in total outlays may be observed because one group has "caught up" to another or because both subgroups have experienced an increase in total outlays but one group has experienced a larger increase than the other. To examine these outcomes, total outlays for selected demographic groups within the young singles sample are compared.

Table 4 shows that, consistent with the larger population of young single adults, no subgroup tested experienced a statistically significant change (increase or decrease) in real total outlays. However, within each subgroup, substantial differences appear in each period observed. For example, total outlays for single men substantially exceed total outlays for single women in each period. Although the gap is larger in 1984–85 (18.5 percent) than in 2004–05 (12.6 percent), the decrease is due to a decrease in total outlays for men, rather than an increase in outlays for women. Nevertheless, the decrease is not statistically significant and

Table 4.	Real total outlays, by demographic group, 1984–85 and 2004–05						
Demographic characteristic	Real total outlays, 1984–85	Standard error	Real total outlays, 2004–05	Standard error	Percent change in real total outlays	*t*-statistic (change in mean of real total outlays)
All young single adults............................	$23,866	663.03	$22,744	531.85	–4.7	–1.32
Men..	25,585	844.92	23,838	722.68	–6.8	–1.57
Women..	21,536	717.51	21,151	637.39	–1.8	–.40
Non-Hispanic:						
White...	24,122	557.19	22,977	638.19	–4.7	–1.35
Black..	23,416	1,975.59	21,644	1,456.91	–7.6	–.72
Hispanic	18,508	4,047.05	21,585	1,400.21	16.6	.72
High school or less...............................	21,617	1,126.33	19,316	877.42	–10.6	–1.61
Some college...	21,283	808.08	19,846	765.83	–6.8	–1.29
College graduate	28,685	1,209.18	27,962	848.94	–2.5	–.49

therefore reveals nothing about the change in relative well-being between young single men and women in this study.

Similarly, Hispanics appear to have the smallest total outlays, on average, in each period, but regardless of the interval studied, the difference in average total outlays is not statistically significant when Hispanics are compared with either group of non-Hispanics. The results—both within 1984–85 and across the time span examined—are more difficult to interpret, though, because of the relatively large variance of total outlays for Hispanics in the earlier period. At the same time, for non-Hispanics, the gap in real total outlays between Whites and Blacks nearly doubled from 1984–85 ($706) to 2004–05 ($1,333). In this case, both groups experienced decreases in average real total outlays, but the decrease for young Black singles ($1,772) was larger than the decrease for young White singles ($1,145). Nonetheless, neither the difference within, nor the difference across, periods was statistically significant for either of these groups.

By contrast, there are clear differences by education level: Those with a college degree have significantly—in both economic and statistical terms—higher total outlays in each period than those who have not earned a college degree. However, there are no statistically significant differences between the two groups of non-college graduates (that is, those with a high school diploma or less and those who attended, but did not graduate from, college).

Regression analysis. In the previous analysis, total outlays are compared for selected subgroups of young single adults, such as men and women. However, such comparisons are limited in usefulness, because it is not clear whether the

total difference in real total outlays, if any, is explained simply by dividing the group into parts for comparison or whether other characteristics within the subgroup differ and it is the differences in these other characteristics that explain the differences in total outlays. For example, single men report larger real total outlays in each year than single women. But is the difference in a person's sex the reason for the difference in outlays, or are single men different from single women in other ways, such as educational attainment or working status, that also may explain differences in real total outlays? And if the latter is true, then to what extent, if any, does a person's sex explain differences in real total outlays? To investigate these issues, regression analysis is used to identify how specific characteristics are related to total outlays, *ceteris paribus* ("all else equal"—that is, when all other characteristics are held constant).

The specific method used in this analysis is called *two-stage least squares*. In the first stage, income data from selected young singles are regressed on independent variables and the results obtained are used to predict income for all young singles in the sample during each period. Then, in the second stage, this new variable is used as an independent variable to estimate total outlays. Reasons for using the two-stage least squares method, as well as a detailed description of the procedure—especially the first stage—are given in "Regression technique: omitted-variable bias and two-stage least squares," in the appendix, pp. 44–49.

Independent variables and control group. Regression analysis allows the researcher to identify whether differences in real total outlays still are expected to be observed when men and women of the same educational attainment,

working status, age, income, and other characteristics are compared. Generally, one set of variables is selected to represent the characteristics of a "typical" member of the group under study, and all others are compared with that "individual." This reference group is often called the *control group*. In the case of binary outcomes (for instance, male or female), the characteristic describing the larger portion of the population is usually selected as the control group characteristic. When more than two outcomes are possible (as in, say, region of residence), the characteristic representing the largest segment of the population is selected. For example, in 1984–85, 17 percent of the sample resided in the Northeast, 25 percent resided in the Midwest, 27 percent resided in the South, and 32 percent resided in the West. Similar percentages hold for the 2004–05 sample. (See table 5.) Therefore, residence in the West is chosen as a characteristic for the control group.

In addition to being regressed against region of resi-

dence, total outlays are regressed against several other characteristics, including age (21 to 24 years or 25 to 29 years); educational attainment (high school or less; some college; college graduate, with or without attending graduate school); student status (working and enrolled full time or part time; or not working, but either currently enrolled or reported "going to school" as the reason for not working during the past year); sex; ethnicity and race (Hispanic; Black, not Hispanic; or White and other, not Hispanic); working status (full time, full year; part time, full year; full time, part year; part time, part year; or not working during the past year for reason other than "going to school"); occupational status (self-employed; or working for a wage or a salary in a position as a manager or professional, technical worker or salesperson, service worker, construction worker, or operator); housing tenure (homeowner or renter); degree of urbanization of area of residence (urban or rural area); number of automobiles owned; number of

[2] At least 50 weeks per year worked.

other vehicles owned; and predicted current income.[43] Also, a binary variable indicating that the young adult was interviewed in 2004–05 is included. This last variable is interacted with (that is, multiplied by) the other variables ("main effect" variables) just listed, in order to ascertain whether the relationship between characteristics and total outlays has changed over time. The control group consists of persons interviewed in 1984–85 who were 21 to 24 years old; had attended college, but were not college graduates; were working full time, full year in a technical or sales position and were not currently enrolled in school; were renters living in urban areas of the West; and did not own any automobiles or other vehicles.[44]

Box-Cox transformation.   When data are not normally distributed, they may exhibit heteroscedasticity, a condition in which the regression error is not constant and standard errors associated with parameter estimates may be biased. However, if the underlying distribution is known, it is possible to transform the variable so that it is—or at least approaches being—normally distributed. For example, if the data are lognormally distributed, then regressing the logarithm of the dependent variable on characteristics should result in unbiased ordinary least squares estimators. At each stage of the analysis, a program was run to find the appropriate Box-Cox transformation of the dependent variable. (See "Box-Cox transformations," in the appendix, p. 43, for details.) In the second stage, the parameter of transformation, λ, was found to be 1/4, indicating that the fourth root was an appropriate transformation of the data. (That is, before regressing, the square root of the square root of observation of total outlays was obtained, and it is this fourth root that is used in the regression.) In the first stage, λ was found to be 3/8.

When λ is found to be either zero or unity, the regression results have appealing attributes, in that the parameter estimates are easily interpreted. (See "Box-Cox transformations," in the appendix, p. 43.) Even so, in the regression performed, the value for λ for both total outlays and income is positive, but less than unity. Therefore, the coefficients of the independent variables do not have any intuitively appealing interpretation. However, in this study, the object is not necessarily to identify *how much* permanent income (for which total outlays is a proxy in the second stage of the regression) has changed for a particular subgroup, but rather to determine *whether* it has changed at all and, if so, *in what direction* (increased or decreased). Fortunately, the parameter estimates are easy to interpret in this way. For example, a positive, statistically significant coefficient for a main effect in the second stage indicates that, in 1984–85,

the main-effect group had higher predicted total outlays than otherwise similar members of the control group. Then, to find out whether changes occurred over time, additional variables are included in which the main-effect variables are interacted with a binary variable indicating the year the interview took place. (See "Regression results," to follow.)

Weighting.   Finally, the regressions are not weighted to reflect the population. The weighting structure in place when the 1984–85 data were collected had changed substantially by 2004–05.[45] Thus, separate regressions would have had to be run to obtain weighted results from 1984–85 and 2004–05. However, in that case, the standard errors of the parameter estimates would be different from what they are when the regression analysis is performed jointly in one model. Therefore, to be able to compare results, the data are pooled and the regressions for each stage are run unweighted.

Regression results.   In considering changes over time in predicted real total outlays, it is useful to describe the outcome for the control group first. The key parameter estimates to consider are those for the intercept, the binary variable indicating the year the interview took place (with a value of 1 for 2004–05 and 0 for 1984–85), and the main and interaction terms for predicted transformed income. If the regression had been linear (that is, if no Box-Cox transformation had been performed), the coefficient of the intercept would represent a baseline value for outlays and the coefficient of income would describe the rate at which outlays are predicted to increase with income, a relationship known as the *marginal propensity to consume.* For example, if the coefficient of the intercept was $1,000 and the coefficient of income was 0.75, this would indicate that young single adults were predicted to spend a baseline value of $1,000, plus 75 cents of every dollar of income received. (That is, the marginal propensity to consume would be 0.75.) The coefficient of the binary variable indicating the year the interview took place would indicate whether there had been an increase (if it were positive and statistically significant) or decrease (if negative and statistically significant) over time in baseline predicted real outlays. The coefficient of the interaction term for income would indicate whether the marginal propensity to consume had increased or decreased over time (again, depending on the level of statistical significance). Although the Box-Cox transformation eliminates the possibility of directly interpreting the coefficients in this way, the actual strategy used in interpreting them is similar. In this case, the coefficients for the intercept and income are both highly significant statistically. However, neither the coefficient of the binary variable indicating the year the in-

terview took place nor the coefficient of the interaction of this binary variable with income is statistically significant. Therefore, there is no evidence to support the hypothesis that there has been a change in real total outlays over time for the control group. Nevertheless, it is interesting to note that the coefficient of the binary variable is negative, a finding that is consistent with the earlier one that real total outlays declined (by almost 5 percent) for all young singles, but that the decrease was not statistically significant.

Some of the remaining results of the regression analysis are consistent with a priori expectations. For example, in each year, real total outlays increase with the number of automobiles and other vehicles owned. Even for vehicles that are not used frequently, one would expect their owners to incur other expenses, such as insurance, maintenance, and, in many cases, loan repayments, that a nonowner would not incur. In addition, there appears to be a relationship between educational attainment and real total outlays. The coefficient of "high school diploma or less" is negative, indicating that in 1984–85 members of this group had lower real total outlays than similar members of the control group (that is, those with some college experience), while the coefficient of "college graduate" is positive, indicating that in 1984–85 members of this group had higher real total outlays than similar members of the control group. However, each of these coefficients is statistically significant only at the 90-percent confidence level. For 2004–05, both coefficients are positive, but neither is statistically significant. Had they been, the positive coefficient would indicate that the positive difference in outlays between college graduates and those who attended college but did not graduate is even larger in 2004–05 than in 1984–85. For those with no college experience, the positive coefficient, which is larger in magnitude than the negative coefficient for the main effect, would indicate that those with lower levels of education in 2004–05 now have real outlays similar to those with at least some college experience. However, because neither of these coefficients is statistically significant, they offer no clear evidence of a change over time in the relationship between real total outlays and educational attainment.

At least one other set of parameter estimates is also worth noting: first, the parameter estimate for Hispanics shows that real total outlays for that group were significantly less than those for non-Hispanics in 1984–85; second, the parameter estimate for 2004–05, while positive, is not statistically significant. Therefore, it cannot be stated with certainty that young single Hispanic adults have seen their real total outlays increase over time. At the same time, however, an *F*-test shows that, although negative (–0.120),

the sum of the parameter estimates for the main effect and its interaction term for Hispanics is not significantly different from zero,[46] indicating that real total outlays for Hispanic young singles are not necessarily lower than those for non-Hispanics, *ceteris paribus*. In other words, there is strong support (due to statistical significance) for the hypothesis that Hispanic young adults had lower real total outlays in 1984–85 than non-Hispanics (due to the negative coefficient). The evidence is less strong in 2004–05. (The sum of the coefficients is still negative, but not statistically significant.) Nevertheless, because the coefficient of the interaction term is not statistically significant, it cannot be stated with confidence that an increase has taken place, because any evidence of increase may be due to variability in the data. Some of this variability may be due to the changing composition of the Hispanic population in the United States over time;[47] however, a definitive answer requires further investigation. At any rate, although the evidence to suggest that Hispanic young adults in the later period are better off than they were in the earlier period is not conclusive, there is no evidence that they are worse off, on the basis of these results.

Of the remaining parameter estimates, only a few are statistically significant in either period. This finding in itself is worth noting, because it means that even though there are differences when averages of real total outlays are compared for different groups, the differences are observed for reasons other than inherent differences in the groups compared. For example, as described earlier, single women have substantially smaller real total outlays, on average, than do single men in each year. This finding is difficult to explain in some ways, because single women have many characteristics that are associated with larger total outlays. For example, more young single women graduated from college in each period than did young single men (38 percent, compared with 31 percent, in 1984–85; 40 percent, compared with 34 percent, in 2004–05), and more own at least one automobile (69 percent, as opposed to 63 percent, in 1984–85; 55 percent, as opposed to 47 percent, in 2004–05). However, for those who reported values for all sources of income that they reported receiving, single women reported substantially lower incomes before taxes—about 20 percent less than men in each period. The regression results indicate that the differences observed in real total outlays for single men and for single women within each year are presumably due to these other differences in demographic characteristics, rather than to inherent differences (such as tastes or preferences) between single men and single women. In addition, the fact that few parameter estimates change in a statistically

significant way over time supports the hypothesis that, although young single adults in the later period may not be better off than those in the earlier period, they do not appear to be any worse off, at least when real total outlays are used as a measure of well-being.[48]

BOTH DEMOGRAPHIC AND SPENDING PATTERNS changed for young, never-married adults from 1984–85 to 2004–05. Whether these changes indicate an increase or decrease in economic status is unclear. By some measures, such as the rate of economic growth and unemployment rates, the more recent group is at least as well off—if not better off—than the earlier group. The more recent group also enjoys higher educational attainment and higher rates of homeownership, both of which are generally considered positive attributes.

However, other results indicate that there has been little discernible change over time. When average real total outlays for subgroups of young single adults, such as men and women, are compared, differences across groups within each period are apparent, but changes within groups across time are not generally observed. These findings are confirmed with regression analysis, which estimates changes in real total outlays over time when demographic differences are held constant. Although it may be interesting to perform Engel or some other, similar analysis on the demographic subgroups, this task is left for future work.

Finally, the evidence that young singles are worse off today is inconclusive. For example, young singles experienced a decrease in real total outlays from 1984–85 to 2004–05, while other singles experienced an increase during that time. However, neither change was statisti-cally significant. In addition, young singles today allocate smaller shares of total outlays to food away from home and to travel, and larger shares to food at home and to housing. Each of these changes would appear to indicate a diminution in economic well-being, yet they are consistent with increased economic well-being as described earlier: the increased share for food at home may be due to the greater availability of convenience foods, allowing young singles to save time and money by "stocking up" rather than frequenting restaurants; and the housing share may have increased because more young singles are living alone, presumably by choice, and also because they are more likely to be homeowners.

Taken together, the results described in this study do not indicate that young singles were clearly better off in the second period than the first, a finding that is consistent with the belief among young adults that it is harder for them to gain economically than it was for their parents.[49] Still, the results do not provide strong evidence that young singles are *worse* off than their predecessors, as has been found in previous work.[50] Given that previous work compared young adults in the mid-1990s with those in the mid-1980s and found a decrease in economic well-being, the current results may indicate that the fortunes of young adults are improving after a period of decline. This finding suggests that future work examining trends in outlays and other measures of well-being for young adults would be useful in order to provide a fuller perspective on what changes have occurred and when they did so. In the meantime, it is valuable to continue to monitor expenditure patterns for young singles to better understand the challenges they face and how such challenges may affect them and others in the future.   □

Notes

[1] According to data from the 1998 Current Population Survey (CPS), 36 percent of 21-year-olds reported graduating from high school as the highest level of education attained, while 7 percent reported completing an associate's degree or higher. Eight years later, in 2006, the CPS indicated that 28 percent of 29-year-olds reported graduating from high school as the highest level of education attained, while 41 percent reported completing an associate's degree or higher level of education. In comparison, that same year, 31 percent of 21-year-olds reported graduating from high school as the highest level of education attained, while 9 percent reported completing an associate's degree or higher level of education. (See "Table 2. Educational Attainment of the Population 15 Years and Over, by Single Years of Age, Sex, Race, and Hispanic Origin: 2006," on the Internet at **www.census.gov/population/socdemo/education/cps2006/tab02–01.xls** (visited May 20, 2008); and "Table 2. Educational Attainment of Persons 15 Years Old and Over, By Single Year of Age, Sex, Race, and Hispanic

Origin: March 1998," from "Educational Attainment in the United States: March 1998 (Update)" (U.S. Census Bureau, report P20–513, issued October 1998), on the Internet at **www.census.gov/prod/3/98pubs/p20–513u.pdf** (visited May 20, 2008). Note that 2006 is the last year for which tables showing educational attainment by exact age were produced.)

[2] For an example of these changing beliefs, see Melinda Crowley, "Generation X Speaks Out on Civic Engagement and the Decennial Census: An Ethnographic Approach," *Census 2000 Ethnographic Study*, June 17, 2003, especially page 2, on the Internet at **www.census.gov/pred/www/rpts/Generation%20X%20Final%20Report.pdf** (visited Sept. 26, 2007). For an example of the changing economic status of young single adults, see Geoffrey Paulin and Brian Riordon, "Making it on their own: the baby boom meets Generation X," *Monthly Labor Review*, February 1998, pp. 10–21; on the Internet at **www.bls.gov/opub/mlr/1998/02/art2full.pdf**.

[6] *Ibid.* See also "2004 Consumer Expenditure Interview Survey Public Use Microdata Documentation," Oct. 18, 2006, p. 103, on the Internet at **www.bls. gov/cex/2004/cex/csxintvw.pdf** (visited Sept. 8, 2008).

[7] In addition to automobiles, major items include other vehicles used primarily for transportation (for example, trucks, vans, and motorcycles) or entertainment and recreation (such as boats and campers). For other items (for instance, apparel) that have been financed by other means (say, by credit card), the expenditures approach applies. That is, the full purchase price is recorded in the reference period during which the purchase was made, even if the balance is not paid immediately. Payments for interest accruing to the balance also are collected during each interview, but the proportion of the total interest accruing to any particular purchase (apparel in the present example) that is included in the total balance, which may also include amounts from other purchases in addition to the amount for the particular purchase, is neither collected nor estimated.

[8] This criterion applies to *all* mortgage principal payments, whether for the home of residence, a vacation home, or some other property. However, regardless of the kind of computation—of expenditures or outlays—mortgage interest, but not the full purchase price, paid for the owned home is included. Nevertheless, information on "purchase price of property (owned home)" is collected, and is included as a component of "net change in total assets" in published tables.

[9] However, actual values for assets and liabilities are not examined here. (See section titled "Limitations of the Data" for more information.)

[10] Excluded from the analysis are cases in which two or more single, never-married adults who share living quarters are either financially interdependent or sharing responsibility for major expenses (or both). By definition, these consumer units consist of at least two members who may be described either as "unrelated persons" (1984–85 and 2004–05) or "unmarried partners" (2004–05), unless they are related by blood or some legal arrangement. Such consumer units are in contrast to single, never-married persons who share living quarters, but who are financially independent and who do not share responsibility for more than one major expense. These consumer units constitute single-member consumer units within the same housing unit. (For more information, see the definition of "consumer unit" in "2004 Public Use Microdata Documentation," p. 299.)

[11] Publications of the 2005 CE data use information from consumer units that were selected for interview under a sample design different from that of consumer units selected for interview in 2004. For technical reasons, only consumer units participating from February through December 2005 were eligible to be selected for interview under the new sample design. Therefore, only information from these consumer units is used in this article when results from 2005 are described. To ensure a proper computation of population counts, the weight of each consumer unit interviewed in 2005 is multiplied by 12/11 before any additional computation is performed. The reason is that 11 months of sample are used to represent 12 months of population. This adjustment does not affect the means or variances of outlays or other characteristics that would have been obtained from the sample of interviews occurring in 2005 and that are used in this study had the adjustment not been made. However, it corrects the population counts, thereby changing the weight of the 2005 interviews in the total sample (that is, interviews occurring in 2004 and 2005) when the means and variances for the 2-year period are computed. For interviews occurring in 2004, no additional adjustment is necessary. Although the sample design used to select consumer units for interview in 2004 is different from the one used in 2005, the same design is used consistently from January through December 2004. Therefore, no adjustment to weights is necessary for consumer units interviewed anytime during that period.

[12] Paulin and Riordon, "Making it on their own," pp. 16, 18.

[13] In 2004, school loans began to be cited as an example when the respondent is asked to report the amount owed for "other credit, such as school loans, personal loans or loans from retirement plans." (See "Consumer Expenditure Survey: Section 21, Part A.1—Credit Liability—Credit Balances—Second Quarter Only" (Bureau of Labor Statistics, Nov. 20, 2005), on the Internet at **www.bls.gov/cex/capi/2004/csxsection21a1.htm** (visited Apr. 9, 2008).) Nevertheless, the proportion of the total amount owed for any of these types of credit separately is neither collected nor estimated.

[14] See "Consumer Expenditure Survey: Frequently Asked Questions (FAQ's)" (Bureau of Labor Statistics, Mar. 4, 2008), on the Internet at **www.bls.gov/cex/csxfaqs.htm#q8** (visited Mar. 25, 2008).

[15] Like asset and liability data, income data are collected less frequently than expenditure data. However, in contrast to asset and liability data, income data are collected not only during the fifth interview, but also during the second interview (or during the earliest interview, in the event that either no respondent was available in time to complete the second interview or the consumer unit originally at the address visited has been replaced by a new consumer unit). Income information from the second (or the earliest) interview is then carried forward to subsequent interviews until it is replaced with information collected during the fifth interview. However, values for assets and liabilities are considered validly blank for records pertaining to all but the fifth interview; that is, no attempt is made to carry the information backward to records pertaining to earlier interviews. Therefore, although information on income is at least potentially available for each consumer unit in the sample, regardless of which particular interview is under consideration (even for those who participate only once), information on assets and liabilities is available only for consumer units participating in the fifth interview, thus limiting its contribution to the analyses conducted herein.

[16] Indeed, the following tabulation from the U.S. Census Bureau shows that the median age at first marriage has risen by about 2 years from 1984–85 to 2004–05 for both men (25 to 27 years) and women (23 to 25 years):

Year	Men	Women
1984................	25.4	23.0
1985................	25.5	23.3
2004................	27.4	25.3
2005................	27.1	25.3

(Source: Table MS-2, "Estimated Median Age at First Marriage, by Sex: 1890 to the Present" (U.S. Census Bureau, Mar. 27, 2007), on the Internet at **www.census.gov/population/socdemo/hh-fam/ms2.xls** (visited May 21, 2008.).)

[17] In the 1984–85 data, educational attainment is described by the highest grade attended and whether or not that grade was completed. For the data from this period, college graduates are defined as those who reported completing the fourth year of college or its equivalent and those who reported attending at least 1 year of graduate school. Those who reported attending, but not completing, 4 years of college are defined as having attended college, as are those who reported attending for 1 to 3 years, even if they reported completing the final year they attended. In the 2004–05 data, educational attainment is described by degree received, including associate's degree (occupational/vocational or academic), bachelor's degree, master's degree, professional school degree, and doctoral degree. For consistency with the 1984–85 data, those who reported receiving a bachelor's degree or higher are defined as college graduates in the 2004–05 data. In addition, those who reported receiving an associate's degree, or attending college but not receiving any degree, are defined in the 2004–05 data as having attended college.

[18] Data from the CPS also show increased levels of educational attainment for young adults. In 1985, 41.4 percent of those aged 20 to 24 years and 43.7 percent of those aged 25 to 29 years had completed at least 1 year of college. In 2005, 55.3 percent of those aged 20 to 24 years and 56.8 percent of those aged 25 to 29 years had completed at least some college. Note that CPS data underwent a change in the definition of educational attainment similar to the change undergone by CE data. In 1985, data are shown by highest level of grade or year of school completed. In 2005, for those who attended college, data are shown for some college but no degree, and for degree received: associate's degree, oc-

cupational/vocational or academic degree, bachelor's degree, master's degree, professional school degree, and doctoral degree. (Sources of data are as follows: "Educational Attainment in the United States: March 1982 to 1985 (P20–415) Issued November 1987: Table 2, Years of School Completed by Persons 15 Years Old and Over, by Single Years of Age, Sex, Race, and Spanish Origin: March 1985" (U.S. Census Bureau, November 1987), on the Internet at **www.census.gov/population/socdemo/education/p20-415/tab-02.pdf** (visited May 20, 2008); Table 1, "Educational Attainment of the Population 15 Years and Over, by Age, Sex, Race, and Hispanic Origin: 2005" (U.S. Census Bureau, Oct. 26, 2006), on the Internet at **www.census.gov/population/socdemo/education/cps2005/tab01–01.xls** (visited May 20, 2008).

[19] Although not measuring an identical sample, data from the National Center for Education Statistics show that college enrollment has increased over time for students graduating from high school. In 1984, 55.2 percent of high school completers were enrolled in college in the October immediately following high school completion. By 2005, the figure had increased to 68.6 percent. Note that these data do not separate enrollment rates for full- and part-time students, nor do they take age into account—presumably, most high school completers in this group are younger than 21, and some are older than 29. Nevertheless, these data are consistent with the findings presented in table 1, namely, that college enrollment has increased for young adults over time. (Source of data is "Student Effort and Educational Progress, Table 25–1, Percentage of high school completers who were enrolled in college the October immediately following high school completion, by family income and race/ethnicity: 1972–2005" (National Center for Education Statistics, 2006), on the Internet at **nces.ed.gov/programs/coe/2007/section3/table.asp?tableID=702** (visited May 21, 2008).)

[20] Data are from tables that were created with online tools ("Create Customized Tables"), on the Internet at **www.bls.gov/cpi/home.htm** (visited Dec. 5, 2006). Data are for "All Urban Consumers (Current Series)" and are not seasonally adjusted.

[21] See "Echoboomerang—number of adult children moving back home—Statistical Data Included," *American Demographics*, June 1, 2001, on the Internet at **www.findarticles.com/p/articles/mi_m4021/is_2001_June_1/ai_76579415** (visited July 17, 2007).

[22] The reference person is the first person mentioned when the respondent in the survey is asked to identify the person who is responsible for owning or renting the home.

[23] Data from the U.S. Census Bureau are consistent with these findings. Specifically, one Census Bureau table shows separately the percentages of men and women 18 to 24 years old, presumably of any marital status, who are classified as "child of householder" in various years. For women aged 18 to 24 years, there is not much change between 1984 (47 percent) and 2005 (46 percent). However, men in that age group exhibit a decline from 62 percent to 53 percent. The reason for this decline is not clear. One possibility is that young men used to live at home during their college years and then moved out after graduation, whereas now they move to campus for their college years and return home after graduation. Whatever the cause, a thorough investigation is beyond the scope of this article. (Source: Table CH-1, "Young Adults Living At Home: 1960 to Present" (U.S. Census Bureau, Mar. 27, 2007), on the Internet at **www.census.gov/population/socdemo/hh-fam/ad1.xls** (visited May 21, 2008).)

[24] See the Bureau of Economic Analysis (BEA) glossary at **bea.gov/bea/glossary/glossary.cfm?key_word=GDP&letter=G#GDP** (visited Jan. 30, 2007).

[25] Growth rates for real GDP were derived from data listed in the Excel file titled "Current-dollar and 'real' GDP" (Bureau of Economic Analysis, Oct. 31, 2007), on the Internet at **bea.gov/national/index.htm#gdp** (visited Nov. 8, 2007).

[26] *Ibid.*

[27] Percentages are derived from *Statistical Abstract of the United States: 2007*, 126th ed. (U.S. Census Bureau, 2006), table 2, "Population: 1960 to 2005."

[28] For definitions of the unemployment rate and the labor force, visit **www.bls.gov/bls/glossary.htm** (visited Jan. 30, 2007).

[29] These data are from computations that were made with annual data obtained with the use of online tools ("Create Customized Tables") that were found on the Internet at **www.bls.gov/cps/home.htm** (visited Jan. 30, 2007).

[30] These statistics exclude marginally attached workers—those who are available and willing to work and who have sought employment in the past 12 months, but not during the past 4 weeks. (For a precise definition of *marginally attached workers*, visit the Web site **www.bls.gov/bls/glossary.htm#M** (visited Nov. 6, 2007).) The statistics also exclude discouraged workers, a subset of marginally attached workers—namely, those who have looked for work in the past 12 months, but are not currently looking because they believe that there are no jobs available for which they qualify. (For a precise definition of discouraged workers, visit the Web site **www.bls.gov/bls/glossary.htm#D** (visited Nov. 6, 2007).) However, no data on either marginally attached or discouraged workers were found for any age group prior to 1994 when the BLS Web site (**www.bls.gov/cps/home.htm**) was last visited (Nov. 6, 2007).

[31] In 1975, the annual unemployment rate for the entire civilian noninstitutional population (that is, a population not limited to young single adults) peaked at 8.5 percent, the highest annual unemployment rate between 1970 and 1979. In 1982, the annual unemployment rate reached 9.7 percent. By contrast, in 1990–91 annual unemployment rose to only 6.8 percent (in 1991), and it was 4.7 percent in 2001. These figures were obtained with online tools ("Create Customized Tables"), on the Internet at **www.bls.gov/cps/home.htm** (visited July 17, 2007).

[32] This is especially true for the group in the earlier period. Many of those aged 21 to 29 years in 1984 would have been members of the labor force in 1981. In July 1981, the seasonally adjusted civilian unemployment rate fell to its lowest point for that year: 7.2 percent. One year later, it reached 9.8 percent. In November and December 1982, it peaked at 10.8 percent. The rate did not return to its 1981 minimum until almost 3 years later, in June 1984. (See "Most Requested Statistics: Labor Force Statistics from the Current Population Survey: Unemployment Rate—Civilian Labor Force—LNS14000000," on the Internet at **data.bls.gov/cgi-bin/surveymost?ln** (Bureau of Labor Statistics, no date) (visited Nov. 29, 2007).) Although the actual rates are different for 20- to 24-year-olds and 25- to 29-year-olds during these periods, the patterns they follow are similar to those for the labor force as a whole. (See "Labor Force Statistics from the Current Population Survey" (Bureau of Labor Statistics, no date), on the Internet at **data.bls.gov/PDQ /outside.jsp?survey=ln** (visited Nov. 29, 2007), accessible by using "One-screen data search" for the database named "Labor Force Statistics including the National Unemployment Rate (Current Population Survey—CPS)" at **www.bls.gov/cps/home.htm#data** (visited Sept. 18, 2008). Seasonally adjusted rates for the 25- to 29-year-old group are not available at this link, but unadjusted rates are.) For many of the younger members of this group (that is, the 20- to 24-year-olds), who, as shown in the tabulation on this page, have higher unemployment rates than the older members of the group (that is, the 25- to 29-year-olds), finding a first job was presumably quite difficult; even for those older members who held jobs prior to 1981, the situation was likely precarious. Undoubtedly, many of them lost jobs due to the recession or had difficulty changing jobs if they desired to. Those who were unemployed not only lacked the ability to add to their savings from the wages or salaries they earned, but also may have had to use their savings to pay for basic goods and services, such as food and housing. By contrast, during the analogous timeframe for the second group, the unemployment rate for the entire civilian labor force was lowest in January and February 2001 (4.2 percent) and eventually peaked in June 2003 (at 6.3 percent). Although never matching the 2001 minimum during the second period, the rate declined from March 2004 (5.8 percent) through December 2005 (4.8 percent). Again, these figures support the hypothesis that young adults in the later period were economically better off than those in the earlier period both during and immediately prior to the years under study.

[33] Milton Friedman, *A Theory of the Consumption Function* (Princeton, NJ, Princeton University Press for National Bureau of Economic Research, 1957); on the Internet at **www.nber.org/books/frie57-1** (visited Aug. 6, 2008).

[34] Starting with the publication of data collected in 2004, multiple imputation began to be used to fill in blanks for income. It will be interesting to use the data obtained therefrom for future cross-generational analyses.

[35] Louis Phlips, *Applied Consumption Analysis* (Amsterdam, Elsevier Science

Publishers B.V., rev. ed., 1983; distributed in the U.S. and Canada by Elsevier Science Publishing Company, Inc., of New York, NY), p. 103.

[36] To better understand this chain of reasoning, suppose that young singles purchase only frozen and freeze-dried prepared foods in both periods, while other consumers purchase different foods. Then adjusting food-at-home expenditures for young singles will overestimate their real expenditures for food at home purchased in 1984–85. If the overestimate is large enough, it will make it appear that young singles had lower expenditures for food at home in 2004–05 than they did in 1984–85. Now, as seen from the values presented in table 2, real expenditures for food at home decrease for young singles when the CPI for all food at home is used to adjust these expenditures. But if young single consumers really did purchase only frozen and freeze-dried prepared foods in each period, then the $1,241 nominal expenditure shown in that table should be adjusted to $1,832 [1,241 × (153.2/103.8)]. Then, because $1,832 is less than the value reported in 2004–05 ($1,950), it follows that young singles actually purchased more food at home in the second period than the first, and they may have done so because they purchased less food away from home, just as the hypothesis purports.

[37] Because rent includes utilities in some cases, comparing only expenditures for rent with outlays for a mortgage does not provide an accurate comparison of basic housing costs.

[38] The other person or persons could be roommates, the landlord, or anyone else not related by blood, marriage, or some other legal arrangement and from whom the young single is financially independent. If any of these conditions is violated, the young single would no longer constitute a single-member consumer unit.

[39] The CPIs for at least three categories of goods and services directly related to travel are readily available on the Internet (**data.bls.gov/PDQ/outside. jsp?survey=cu** (visited Dec. 5, 2007), accessible by using "One-screen data search" for the database named "All Urban Consumers (Current Series) (Consumer Price Index—CPI)" at **www.bls.gov/cpi/home.htm#data** (visited Sept. 18, 2008)). In each case, the increase in the CPI for these categories is higher than the increase in the CPI for all goods and services from 1984 to 2005 (88 percent). The categories are "other lodging away from home, including hotels and motels" (157 percent); "gasoline (all types)" (99 percent); and "airline fare" (243 percent). Changes in annual indexes are compared in this case, instead of changes from January 1984 to December 2005, in order to reduce the effects of intrayear volatility. Prices for each of these travel expenditure categories presumably vary by season if not by month, so comparing values for different months across years, rather than comparing average annual values, may either mitigate or exacerbate differences in price changes computed. In addition, seasonally adjusted indexes are not available for airline fares in years prior to 1989.

[40] Evidence supporting the hypothesis that consumers substitute new forms of communication for travel is seen in the CE results. The trend line for the percentage of those reporting total travel expenditures is much steeper downward from 1997 to 2005 than it is from 1984 to 1996, a pivotal year that coincides with a period of rapid increase in usage of these technologies. For example, the U.S. Census Bureau reports that in 1997 less than three-eighths (36.6 percent) of all households owned a computer and that about half of these households (18.0 percent of all households) had Internet access. By 2003, nearly five-eighths (61.8 percent) of all households owned a computer and nearly eight-ninths of these households (54.7 percent of all households) had Internet access. (See Jennifer Cheeseman Day, Alex Janus, and Jessica Davis, "Computer and Internet Use in the United States: 2003," *Current Population Reports*, P23–208, October 2005, pp. 1–14, especially p. 1, on the Internet at **www.census.gov/population/www/socdemo/computer.html**, item 1, CPS, October 2003, "Report" (visited

Dec. 5, 2007).

[41] For all consumer units, college tuition accounted for 58 percent of educational expenditures in 1984–85 and 64 percent in 2004–05.

[42] The increase in education expenditures presumably also affects the allocation of shares for those who pay them. That is, given the same amount of funds available for spending, the person who allocates more to education has less to allocate to food, housing, and all other goods and services. However, separating out those who make these expenditures from those who do not and comparing the differences in their share allocations, both within and across various periods, is beyond the scope of this discussion.

[43] See "Regression technique: omitted-variable bias and two-stage least squares," in the appendix, pp. 44–49, for variables used to predict income and for other details about the first stage of the regression.

[44] In 1984–85, more than half—almost 59 percent—of young, single adults who were sampled reported ownership of (exactly) one automobile. However, in 2004–05, the figure dropped to 48 percent, which was equal to the percentage reporting no automobile owned. For convenience, the control group consists of those owning no automobiles. In this way, changes in the parameter estimate for number of automobiles owned need not be taken into account in describing changes in predicted real outlays over time for the control group.

[45] The weighting method used in CE publications is *balanced repeated replication*, a technique in which means and variances are estimated several times with the use of weighted half-samples. In 1984–85, only 20 replicate weights were available to compute such estimates. By 2004–05, 44 replicate weights were available.

[46] *F*-value = 0.74; *p*-value = 0.3892.

[47] For details, see Geoffrey D. Paulin, "A changing market: expenditures by Hispanic consumers, revisited," *Monthly Labor Review*, August 2003, pp. 12–35, especially pp. 12–16; on the Internet at **www.bls.gov/opub/mlr/2003/08/art2full.pdf**.

[48] As mentioned, in this study total outlays are regressed on many characteristics, including predicted income. Therefore, many variables may lack statistically significant coefficients because, given the same income, members of the groups associated with these variables have average outlays that are similar to those of the control group. However, as with single women, perhaps current income differs for the groups under study, and this difference, rather than the demographic differences of interest, influences the outcome for total outlays. In some cases, in fact, coefficients used to predict current income are statistically significant for both the main and interaction effects. For example, the coefficient for single women is negative and statistically significant in the current income regression. However, the interaction term for women and the variable indicating interviews that took place in 2004–05 is positive and statistically significant. The sum of these values (−1.718) is still negative and is statistically significantly different from zero (*F*-value = 12.59; *p*-value = 0.0004). The positive statistically significant coefficient for the interaction term indicates that women have experienced increases in predicted income over time. However, the negative statistically significant sum indicates that women are still predicted to have lower incomes than single men in the later period, at least for those who provide values for all sources of income that they reported receiving. (For the complete set of regression results used to obtain predicted income, see table A-3, in the appendix, pp. 45–46.)

APPENDIX: Notes on methodology

Accounting for intertemporal changes

Analyzing shares.   In analyzing shares, the allocations of total outlays for two different groups are compared to find out which group is better off. To understand this idea, consider two single persons, each of whom purchases the same amount of food each week for $20. Suppose the first person has the lower income and spends $100 per week on all purchases; the second person spends $200 per week. Then the share of expenditures allocated to food is 20 percent for the first person, but only 10 percent for the sec-

ond, even though the same amount of food is purchased. Even if the second person buys more, or higher quality, food for $30, the share increases only to 15 percent. In each case, the second person has a larger portion of spendable dollars left over to purchase goods and services other than food than does the first person; therefore, the second person is considered to be better off.

Although analyzing shares is particularly useful for comparing groups within the same period, there are some caveats to consider in analyzing changes in shares over time. For example, important information can be masked by price changes. To see this effect, consider a person who enjoys apples as an occasional snack and budgets $10 per month for their purchase. If the price of apples is $1 per pound, this person can afford 10 pounds per month. If the price rises to $2 per pound, the person can afford only 5 pounds per month. If no other prices change, and the person's expenditure pattern remains the same in all other respects, then the share of total outlays allocated to apple purchases remains the same each period, yet the person is enjoying fewer pounds of apples.

If, then, the change in the price of apples is known, expenditures can be adjusted, and it becomes clear that the person is purchasing fewer pounds of apples. In the current example, the price of apples has doubled. Therefore, if the person bought the apples in the first period at the price of the second period, then the expenditure in the first period would be double the value observed. (That is, 10 pounds of apples purchased at the price of the second period would cost $20, not $10.) Because the price-adjusted outlay for the first period ($20) is larger than the observed outlay for the second one ($10), it is clear that the number of pounds of apples purchased has declined in the second period. This relationship (higher price-adjusted expenditures mean a larger quantity purchased) holds even when the actual number of pounds of apples (or quantity of other goods and services) purchased is unknown, as it is for the values shown in table 2 in the text.[1]

In addition, the allocation of total outlays changes with tastes and preferences, which in turn can change over time for individuals or groups. In cases such as these, in which both kinds of change occur, changes in shares are not so easy to interpret. For example, as discussed in the text, the share for food away from home has been decreasing over time, while the share allocated to food at home has been increasing. Assuming that food away from home is preferred to food at home, this outcome reflects a decrease in well-being. However, if young adults in the second period have a higher preference for education than they did in the first period, they may forego some of the expenditures for food away from home in order to purchase education, even if the costs of education remain stable. In that case, if the increase in well-being due to purchasing more education is larger than the decrease due to purchasing less food away from home, then young adults in the second period are better off than they would be if they did not make such a tradeoff.

Finally, changes in technology and in the availability of products can influence the allocation of total outlays. As noted in the text, the availability of new types of food at home may lead to changes in purchases such that the increased share for food at home and decreased share for food away from home reflect an increase in well-being. Similarly, changes in technology or in the availability of products may lead less directly to changes in certain shares. For example, young adults in the first period may have purchased food away from home in conjunction with entertainment away from home (as when they go out for dinner and a movie). Although they still may do so in the second period, new products or services may have been developed that allow young adults to enjoy similar forms of entertainment at home (for instance, joining a movie-by-mail rental club or viewing movies over the Internet). In this case, the share for food away from home could decrease while both the share for food at home and well-being increase, because young adults in the second period could still choose to purchase the same amount of food and entertainment away from home as those in the first period did, but they also are able to choose an allocation that was not available in the first period.

Because no data on tastes, preferences, technological change, or the availability of products are collected directly in the CE, it is impossible to identify precisely how these factors change and how expenditure patterns change as a result. Nevertheless, despite these caveats, analyzing shares in a historical context is useful as long as the assumptions underlying the analysis are reasonable and explicitly stated as needed.

Real or nominal expenditures?   In performing economic comparisons across time, it is essential to control for changes in prices. To demonstrate, consider a person who spends $10 for apples in the first period and $20 in the second. It may be that the person purchased twice as many pounds of apples in the second period. But it also may be that the price changed (rose or fell) and the person purchased a different amount each period. For example, if the price of apples is $1 per pound in the first period, but $4 per pound in the second, it is clear that the person bought a greater amount of apples (10 pounds) in the first period than in the second (5 pounds). Usually, expenditures can be adjusted to reflect these changes by converting nominal expenditures to real expenditures through the mechanism of a price index. After adjustment, real expenditures can be compared to provide a better idea of whether changes in expenditures are due to changes in quantities purchased or changes in prices.

Price indexes are computed by comparing changes in price for a standard market basket of goods. In this case, the basket consists only of apples. Once the basket is defined, the index is computed by dividing the price of the basket in the period of interest by the price of the basket in the base period and multiplying the result by 100.0. In the base period, the period of interest and the base period are the same. Therefore, the index in the base period is always 100.0. However, if prices are different in the period of interest, the index will take on a higher or lower value, depending on the direction of the price change. For example, if the first period is selected as the base period and the

basket is defined as consisting of 1 pound of apples, then the base-period index is computed to be ($1/$1) × 100.0 = 100.0. The index for the second period is ($4/$1) × 100, or 400.0.

Once the indexes are computed, they can be used to convert nominal expenditures to real expenditures. In the current case, suppose the analyst wants to convert the nominal value of expenditures reported in the first period to real-dollar values for comparison with expenditures occurring in the second period. In other words, the analyst wants to know how much the market basket purchased in the first period would have cost if it had been purchased in the second period. The result is obtained by dividing the price index for the second period by the price index for the first period and multiplying the result by the expenditures reported in the first period. In this example, then, the equation is (400.0/100.0) × $10 = $40. In other words, in the second period it costs $40 to purchase the same amount of apples that was purchased in the first period. Even if the quantity of apples purchased is unknown to the analyst, it is clear that the purchaser must have purchased fewer pounds of apples in the second period than in the first, because the value of real expenditures reported in the first period (that is, $40) exceeds the value of real expenditures reported in the second period (that is, $20).[2]

Note that this adjustment works because expenditures are defined as price (P) times quantity purchased (Q). Therefore, if P_1Q_1 (that is, the expenditure in the first period) differs from P_2Q_2, it is not clear whether the difference is a result of changes in P or in Q. However, adjusting first-period expenditures in the manner just described has the effect of comparing P_2Q_1 with P_2Q_2. Therefore, any difference in expenditure is due to a change in quantity.

However, the comparison is not always so precise. In this case, the analyst is literally comparing apples with apples. Suppose, however, the consumer purchases both apples and oranges. This purchase leads to a potential comparison of two different baskets of fruit. That is, suppose that the initial basket consists of 1 pound of apples and 1 pound of oranges. Suppose also that the price of apples remains unchanged, but the price of oranges rises. Then the price index for fruit will rise, because it reflects the change in the total price of a basket of fruit consisting of 1 pound of apples and 1 pound of oranges. However, in response to the price change, the consumer may choose to purchase fewer pounds of oranges and continue to purchase 1 pound of apples. Alternatively, the consumer may substitute apples for oranges (that is, purchase more than 1 pound of apples and less than 1 pound of oranges) or may indeed purchase less than 1 pound of each fruit. Only if the consumer continues to purchase 1 pound of apples and 1 pound of oranges after the price change will the index perfectly adjust nominal expenditures in the first period to values that are to be compared with those observed in the second period.[3]

Nevertheless, using the price index to convert nominal expenditures to real expenditures is important. Although the results may not provide a perfect adjustment to the first-period expenditures for comparison over time, they still provide better information for analysis than a comparison of unadjusted values. Like any tool, a price index has to be used cautiously and correctly, and the analyst has to be aware of both its uses and its limitations before drawing analytical conclusions.

Statistical procedures

Adjusting expenditures for food at home.   In the Interview component, or Interview Survey, of the CE, data on expenditures for food at home are collected by means of two questions. Prior to 1988, the first question asked about monthly expenditures for food at grocery stores and the second asked about monthly expenditures for food at other stores, such as convenience stores. In 1988, each question was changed to ask about weekly expenditures for these items. From 1987 to 1988, average expenditures for food at home for young single adults rose 44.8 percent. By contrast, from 1984 to 1987 the average annual increase (2.5 percent) was similar to the average annual increase from 1988 to 2005 (1.9 percent).[4] Because the change in these expenditures in any single year other than from 1987 to 1988 ranged from −9.8 percent (from 1992 to 1993) to 8.6 percent (from 2003 to 2004), the large change from 1987 to 1988 is presumably due to the change in the two questions.

Some of the change may be due to the way in which respondents think about the questions, as well as the way in which the processing of the data changed starting in 1988. When asked to report monthly expenditures, respondents may have thought about weekly expenditures, which they then multiplied by 4 before reporting. For example, a respondent with $50 in usual weekly expenditures would have reported $200 per month. During processing, these monthly reported expenditures were multiplied by 3 to produce quarterly estimates, because there are 3 months per quarter. In this example, $600 would be the resulting quarterly expenditure estimate. However, when weekly expenditures are collected directly, they are multiplied by 13 to obtain quarterly estimates, because there are 13 weeks per quarter. Thus, the quarterly estimate would be $650, not $600. However, if the hypothesis presented here is correct, then quarterly expenditures are expected to rise about 8 percent due to the change in the questionnaire, because, essentially, reported expenditures are being increased by about one-twelfth. (That is, when monthly expenditures are multiplied by 3, only 12 weeks of expenditures compose the quarterly estimate, whereas, since 1988, an extra week is included in the composition of the quarterly estimate). Of course, even if this hypothesis is correct, expenditures for 1988 could increase by more or less than 8 percent, due to changes in prices or other exogenous factors that contribute to the natural variation in expenditures for food at home from year to year. Still, the increase of nearly 45 percent strongly reduces the credibility of the aforementioned hypothesis, especially because data on expenditures for food at home (excluding food prepared by the consumer unit on out-of-town trips) published in standard tables, which are derived from the Diary component, or Diary Survey, of the CE, do not show

such a change from 1987 to 1988.[5] Therefore, to account for the change—whatever its cause—requires an adjustment more complicated than adding 8 percent to reported expenditures in order to make expenditures in 1984–85 more comparable to those reported in 2004–05.

To start, it is important to note that in the Interview Survey, as mentioned, information on expenditures for food at home excluding food prepared on trips consists of data collected from two questions: one on food purchased from grocery stores, the other on food purchased from other stores, such as convenience stores. Both questions changed in 1988 to request usual weekly, rather than monthly, expenditures. Each question was affected by the change in the magnitude of the response to it: for those reporting expenditures at grocery stores, the expenditure increased more than one-third (37 percent); however, for those reporting expenditures at other stores, the expenditure more than doubled (rising almost 104 percent). Nevertheless, the change in the questions does not appear to have affected the *rate* of response to them: from 1986 to 1989 (that is, the last 2 years of the monthly question and the first 2 years of the weekly question), the percentage of respondents reporting purchases at grocery stores ranged from 95.9 percent (1986) to 96.8 percent (1989), while the percentage reporting purchases at other stores ranged from 40.4 percent (1988) to 42.0 percent (1987).

The next step is to estimate the values that would have been reported in 1984 and 1985 had the questions asked about usual weekly, rather than monthly, expenditures. One method is simply to adjust the 1984 and 1985 expenditures by the percent change reported from 1987 to 1988. Consider, for example, expenditures at grocery stores. As mentioned earlier, the change in the mean for young singles who report these expenditures was 37 percent. Therefore, multiplying these expenditures, as reported in 1984 and 1985, by 1.37 would increase them by the appropriate amount. However, this method is too simplistic, for when the 1987–88 change is omitted, the percent change in expenditures at grocery stores ranges from −9.8 percent (from 1992 to 1993) to 9.1 percent (from 1991 to 1992). Even excluding this period of volatility (from 1991 to 1993), the percent change ranges from −2.8 percent (from 1988 to 1989) to 7.5 percent (from 1999 to 2000). Therefore, it is difficult to say how much of the 37-percent change is due to the change in the questionnaire and how much is due to natural variation in reported expenditures. Simply multiplying expenditures reported in 1984 and 1985 by 1.37 may substantially over- or underestimate the values that would have been reported if usual weekly expenditures had been collected then.

Instead, regression is used to estimate the adjustment factor. In each regression (run separately for grocery store expenditures and other store expenditures), for those reporting expenditures in each year, the natural logarithm of the mean value of their expenditures is regressed on certain variables (described subsequently), the values of which depend on the period. The purpose of this logarithmic model is to use a formula that is well known in finance, namely, $A_t = A_0 e^{rt}$, where A_0 is the ini-

tial amount invested in an account, r is the rate of growth (for example, the interest rate) of the investment, t is the number of periods, e is a transcendental number equivalent to approximately 2.718, and A_t is the amount in the account in the final period. In the study of expenditures, r is the average annual rate of change of expenditures and can be calculated when other variables in the equation have known values. In the present case, the mean value for young singles who reported grocery store expenditures in 1984 was $A_0 \approx \$216$. In 1987, the value was $A_t \approx \$229$. Accordingly, by what rate would expenditures have to have increased each year to meet these conditions? To find out, the natural logarithm of both sides of the earlier equation is taken, or $\ln(A_t) = \ln(A_0) + rt$. From this point forward, r can be found with standard algebra, given that t is 3 (because the initial \$216 grew for 3 years after 1984—that is, from 1984 to 1985, from 1985 to 1986, and from 1986 to 1987).

Although this method describes the average annual growth rate necessary to move from the values observed in 1984 to those observed in 1987, the rate obtained may be affected by random variation in the data. That is, suppose that a drought or some other event caused prices, and therefore expenditures, to be higher than usual in 1984, but that they returned to their expected level in 1987. Then the average annual growth rate computed in this way would underestimate the actual underlying long-term growth rate, because expenditures in 1984 would have started at a higher level than expected and therefore would need to increase less swiftly each year to reach the expected 1987 level than they would have had observed values equaled expected values in both years. To estimate both the initial expected starting value and the underlying long-term growth rate, then, regression is used. Note that when the natural logarithm of expenditures is regressed on time values, the intercept of the equation estimates $\ln(A_0)$—the logarithm of the expected value of expenditures when t equals zero—and the coefficient of t is the estimated average annual growth rate for the long-term trend.

Before performing the regression, it is important to note that the change in question may have affected not only the intercept of the equation, but also the rate at which reported expenditures change over time. To find out, a single regression is run so that the coefficients of the intercept and slope for the 1984–87 equation can be compared with those for the 1988–2005 equation. The equation for the regression is

$$\ln(A_t) = c_1 B_1 + c_2 B_2 + r_1 B_1 t + r_2 B_2 t + u.$$

In this regression, binary variables are used for convenience in place of the traditional intercept. The first binary variable (B_1) equals unity for the years 1984 through 1987 and zero for 1988 through 2005. The second binary variable (B_2) equals zero for the initial years (1984 through 1987) and unity for the later years (1988 through 2005). Next, each year is assigned a value t for the period it represents. For 1984, t equals zero; for 2005, t equals 21. This time variable is not included separately in the

model; however, it is multiplied by each of the binary variables just described, and these interaction terms are included in the model. The coefficients c_1 and c_2 of the binary variables provide the estimated intercept for each of the periods, while the coefficients r_1 and r_2 of the interaction terms provide the estimated long-term growth rates for each model. (The final term, u, is the error term.) As expected, the difference of the coefficients of the binary variables is statistically significant, indicating that there was a change in reported values when the new question was introduced. However, the difference of the coefficients of the interaction terms is not statistically significant, as shown by an F test.[6] Therefore, the hypothesis that the question had no effect on the underlying trend is reasonable on the basis of the evidence.

With the regression results computed (see table A-1), the coefficients of the binary variables are used to calculate the adjustment factor. Note that the coefficient of the second binary variable provides an estimate of what the natural logarithm of reported expenditures would have been in 1984 had the weekly, rather than monthly, question been asked then. To find out the estimated value that actually would have been reported, this coefficient is exponentiated, yielding $212.42. Similarly, the coefficient of the first binary variable is exponentiated, yielding the estimated value ($282.01) for expenditures in 1984 in the absence of random variation that removed reported values from their underlying trend line. The ratio of these two values is about 1.3276; that is, the change in the question is estimated to have raised expenditures by about 32.8 percent. Therefore, this ratio is used as the adjustment factor for food purchased at grocery stores in 1984 and 1985. A similar analysis shows that

the estimated factor for food purchased at other stores is about 1.6825. (See table A-2 for regression results.)

Once found, expenditures for each type of purchase are multiplied by their adjustment factor, and food at home expenditures in 1984–85 are computed from these adjusted values. To test the adjustment, the unadjusted change in average expenditures for food at home from 1987 to 1988 is compared with the adjusted value. As noted in the text, prior to adjustment, expenditures for food at home excluding food prepared on trips rise nearly 45 percent from 1987 to 1988. However, after the adjustment, the percent change is 5.9 percent, a value that is within the range (from –2.8 percent to 7.5 percent) for changes in observed (that is, preadjusted) values, even when observations from the most volatile period (1991 to 1993) are excluded. Perhaps more important, after adjustment, the components also demonstrate reasonable changes in the mean for those reporting from 1987 to 1988.[7] Given that this finding is reasonable, the adjustment factors are accepted. Finally, as noted in the text, other values, such as total food expenditures, total outlays, and "all other outlays" (that is, total outlays less food, shelter and utilities, and other items listed in table 2 in the text), are then computed from these adjusted values.

An alternative method to that just described is to exponentiate the intercepts as described, subtract the 1984–87 value from the 1988–2005 value, and add the resulting difference to each of the observations in the data set before computing results for food at home. Either method would result in the same mean for expenditures for food at home excluding food prepared on trips. However, in the alternative method, the variance of each component that would be computed prior to

Table A-1.	Regression results for computing adjustment factors for expenditures for food purchased at grocery stores[1]					
Variable	**DF**	**Parameter estimate**	**Standard error**	**t value**	**Pr > |t|**
Year 1984–87 (B_1)	1	5.35857	0.02370	226.06	<.0001
Time 1984–87 (B_1t)	1	0.01858	0.01267	1.47	0.1599
Year 1988–2005 (B_2)	1	5.64193	0.01742	323.87	<.0001
Time 1988–2005 (B_2t)	1	0.02360	0.00129	18.34	<.0001

Computation of factor: (exp(5.64193))/(exp(5.35857)) = 1.327583.

[1] Dependent variable: Natural logarithm of mean expenditures for food purchased at grocery stores.

Table A-2.	Regression results for computing adjustment factors for expenditures for food purchased at other stores[1]					
Variable	**DF**	**Parameter estimate**	**Standard error**	**t value**	**Pr > |t|**
Year 1984–87 (B_1)	1	4.19795	0.06290	66.74	<.0001
Time 1984–87 (B_1t)	1	–0.01903	0.03362	–0.57	0.5784
Year 1988–2005 (B_2)	1	4.71821	0.04622	102.07	<.0001
Time 1988–2005 (B_2t)	1	0.02188	0.00342	6.41	<.0001

Computation of factor: (exp(4.71821))/(exp(4.19795)) = 1.682465.

[1] Dependent variable: Natural logarithm of mean expenditures for food purchased at other stores.

the adjustment would be unchanged after the adjustment. The result would be a larger mean with the same standard error of the mean for each component, thus increasing the likelihood that differences over time for the aggregate expenditure (that is, food at home excluding food prepared on trips) would be statistically significant.

In contrast, using the percentage adjustment factor allows the variance of each component to increase in proportion to the increase in the mean of each component. That is, if the mean for food purchased at grocery stores rises by 37 percent, so will the standard error of the mean for that component. Similarly, adjusting separately each of the components of expenditures for food at home excluding food prepared on trips allows for a larger variance in the recomputed aggregate expenditure than performing the regression directly on mean expenditures for food at home excluding food prepared on trips. The reason is that some respondents report expenditures only for food at grocery stores, some report expenditures only for food at other stores, and some report both. Because the adjustment factors differ for each of the components, the percent increase in total expenditures for food at home excluding food prepared on trips will differ for each type of respondent, which in turn will increase the variance among respondents. As noted, the larger variance makes the analysis of change more conservative. That is, the threshold for finding a statistically significant difference is higher when the variance is higher, and therefore the analyst can be more confident in accepting the results. This conservative approach is especially important given that the data have undergone adjustments which are themselves based on estimates rather than reported values.

Box-Cox transformations.   Expenditure data are not often normally distributed, a situation that can cause bias in regression results.[8] However, expenditure data can be transformed so that they are *approximately* normally distributed. One method that has been used is the Box-Cox transformation.[9] Perhaps the most frequently cited version is

$$Y^* = (Y^\lambda - 1)/\lambda, \qquad (1)$$

where Y^* is the transformed version of the variable, Y denotes expenditures for a specific good or service (for example, food at home or apparel), and λ is a parameter. This version of the equation is most useful in demonstrating two special cases for the value of λ:

1. If λ is equal to unity, then no transformation of the independent variable is necessary. (The net result is that Y^* equals $Y - 1$, and subtracting a constant from each observation of Y will not affect the distribution.)
2. If λ approaches zero, then Y^* is approximately equal to the natural logarithm of Y.

Although this specification is useful for deriving the value of Y^* when λ approaches zero, it does not yield an intuitive inter-

pretation when λ takes on any other value.[10] However, in their original article, Box and Cox point out that equation (1) can be simplified to

$$Y^* = Y_\lambda.$$

This equation leads to a simple interpretation of both λ and the equation as a whole. In the current study, λ is found to be 1/4 for total outlays, indicating that the transformed variable is then simply the fourth root of Y. For income before taxes, λ is found to be 3/8, or the eighth root of the cubed income before taxes.[11]

The Box-Cox transformation is particularly useful in two special cases: when the results confirm that no transformation is required (that is, when λ, the transformation factor, equals unity) and when a logarithmic transformation is appropriate (that is, when λ equals zero). In these cases, the parameter estimates are intuitively interpretable. For example, if untransformed outlays are regressed on binary variables, the parameter estimates of those variables show how much more (or less) the group defined by the variable spends than a similar member of the control group. For example, if the coefficient of *rural* is 0.05, then rural residents spend 5 cents more, on average, than urban residents, *ceteris paribus*. If untransformed outlays are regressed on untransformed income, then the parameter estimate on income is equal to the marginal propensity to consume, which is the portion of each additional dollar that is expected to be allocated to total outlays, at least in the current study. (That is, if the parameter estimate of income is 0.05, then total outlays are predicted to increase 5 cents each time income increases by 1 dollar.) Similarly, if logarithmically transformed outlays are regressed on untransformed income and other variables, then the coefficient, if small, describes the percent change in outcome, given the group change. (As an example, if the coefficient of *rural* is 0.05, then those in a rural area spend 5 percent more than those in an urban area. If the coefficient of untransformed income is 0.05, then each dollar increase in income is predicted to lead to a 5-percent increase in total outlays.) Finally, if logarithmically transformed outlays are regressed on logarithmically transformed income, then the parameter estimate of income is an estimate of income elasticity—that is, the predicted percent change in total outlays, given a 1-percent change in income.

The obvious question raised is how the value of λ is found. Conventionally, this is done by trial and error. Several values for λ are used, and whichever yields the model with the lowest mean square error is the selected value. However, this method is extremely time consuming, especially because two variables (total outlays and predicted current income) are being transformed. In this study, λ is estimated through a maximum-likelihood procedure used by Stuart Scott and Daniel J. Rope in their 1993 study of Consumer Expenditure Survey data.[12]

Measuring statistical significance: types and computations of t-*statistics.*   As noted in the text, a difference in two parameters, such as means, is considered to be statistically significant if it is not likely to be due to chance alone. A common statistic used

to measure the probability that a difference is due to chance alone (and thus is, or is not, statistically significant) is the t-*statistic*. When samples are large, a *t*-statistic greater than 1.96 in absolute value indicates that the probability that a difference in parameters is due to chance alone is less than 5 percent.

The formula for computing the *t*-statistic depends on what type of comparison is being performed. Perhaps the most common use of the *t*-statistic is for comparing means. In the text, for example, average annualized real total outlays are compared for young singles in two different periods. The samples are therefore independent and are assumed to have different variances. In this case, the formula for computing the *t*-statistic is

$$\frac{x_2 - x_1}{\sqrt{SE_2^2 + SE_1^2}},$$

where x_i is average annualized real total outlays in period i (1984–85 or 2004–05) and SE_i is the standard error of the mean in period i.

In table 4 in the text, average annualized real total outlays for all young singles is shown to be \$23,866 in 1984–85 and \$22,744 in 2004–05. The standard errors associated with these means are 663.03 and 531.85, respectively. Therefore, the *t*-statistic is computed to be

$$\frac{22,744 - 23,866}{\sqrt{531.85^2 + 663.03^2}} = -1.32.$$

Because the absolute value of the *t*-statistic (1.32) is less than the critical value (1.96), the probability that the difference in means (a decrease of \$1,122) is due to sampling error or other random events is greater than 5 percent; therefore, the difference is not statistically significant at the 95-percent confidence level.

However, testing differences in means is not the only use for *t*-statistics: they also can be used to detect statistically significant differences in *proportions*. For example, table 3 in the text shows that, in 1984–85, 64 percent of all households with *at least* one young single person were households with *only* that young single person. (That is, 36 percent of these households included at least one other person, regardless of age or marital status.) In 2004–05, that proportion increased to 77 percent. The critical value to test whether these proportions reflect a change in the composition of households is still 1.96; however, the formula for computing the *t*-statistic changes to

$$\frac{p_1 - p_2}{\sqrt{p_3(1 - p_3)\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}},$$

where p_1 is the proportion of households with exactly one young single person in 1984–85 (that is, 1,252/1,953); p_2 is the proportion of households with exactly one young single person in 2004–05 (that is, 1,401/1,811); p_3 is the "pooled" proportion (that is, [1,252 + 1,401]/[1,953 + 1,811]); n_1 is the sample size in 1984–85 (that is, 1,953); and n_2 is the sample size in 2004–05 (that is, 1,811). The outcome of this test is similar to that of a chi-square test; in fact, the *t*-statistic equals the square root of the chi-square statistic computed by means of a chi-square test.

In addition, there is a special formula for comparing differences in *shares* across groups. A special formula is needed for this type of comparison because the value being measured is a ratio of two other variables that not only have their own means and standard errors, but also are not independent of each other. For example, because food at home is a component of total outlays, the covariance of mean expenditures for food at home and total outlays is expected to be positive. That is, as expenditures for food at home rise, so do total outlays, assuming that all other outlays are held constant. Accordingly, in this case, before computing the *t*-statistic, it is necessary to compute the variance of the share for each year. The formula for the variance of the share in a particular year is[13]

$$V(S) = (\frac{1}{n})[\frac{F^2}{T^4}V(T) - 2(\frac{F}{T^3})\text{cov}_{F,T} + (\frac{1}{T^2})V(F)],$$

where n is the sample size (2,359 for 1984–85 and 2,158 for 2004–05); F is the average expenditure for food at home; T is the average of total outlays (including food at home); $V(i)$ is the sample variance of the expenditure or outlay; and $\text{cov}_{F,T}$ is the covariance of food at home and total outlays.

Note that $V(i)$ is the variance of the observations in the sample, not the variance of the mean obtained from the sample. That is, $V(i)$ measures how the observations vary around the mean of the sample, rather than estimating how means of similarly sized samples drawn from the same population would vary around the population mean. In other words, $V(i)$ is the square of the sample standard deviation, and $V(i)/n$ is equal to $(SE_i)^2$. Therefore, the previous formula can be rewritten as

$$V(S) = [\frac{F^2}{T^4}(SE_T)^2 - 2(\frac{1}{n})(\frac{F}{T^3})\text{cov}_{F,T} + (\frac{1}{T^2})(SE_F)^2].$$

For convenience, this equation simplifies to

$$V(S) = (\frac{1}{T^2})[((\frac{F}{T})SE_T)^2 - 2(\frac{1}{n})\frac{F}{T}\text{cov}_{F,T} + (SE_F)^2],$$

where F/T is the value of the share (that is, the ratio of the averages) undergoing testing.

Because $V(S)$ equals the squared standard error of the share (and not the squared standard deviation of the share), the formula for the *t*-statistic is now

$$\frac{S_2 - S_1}{\sqrt{V(S_2) + V(S_1)}},$$

where $S_i = F_i/T_i$. Once again, the critical value in this case is 1.96.

Regression technique: omitted–variable bias and two–stage least squares. Income data in household surveys are subject to nonresponse. That is, a person may not know or may not report the value of a particular source of income received, even when the income is reported as having been received. Starting with the publication of the 2004 data, the CE has used multiple imputa-

tion to fill in missing values. However, prior to that time, other methods were used to adjust for nonresponse.[14] Starting with the publication of the 1972–73 survey results, consumer units were classified as either "complete" or "incomplete" reporters of income. In general, complete reporters provided a value for at least one major source of income, such as wages and salaries, self-employment, or Social Security. However, even complete income reporters did not always provide a full accounting of income from all sources.

Using income information just from complete income reporters is problematic. First, the fact that some of the respondents provide only partial information (for example, the respondent may report a value for wages and salaries, but may not know the value of interest income, which also is reported as having been

Predicted real income, transformed, 2004–05	1	.00825	.02477	.33	.7392

received) introduces measurement error into the regression. Even if the sample is reduced just to respondents who reported values for each source of income that they reported as having been received (call them "nonmissing" income reporters for the purposes of this discussion), mean income and parameter estimates obtained from this sample are biased, unless the reduced sample is a random subset of the population.[15] Unfortunately, the assumption that the reduced sample is drawn randomly from the population is not realistic either generally or for young single adults, the group under study in this article. For example, in 2004–05, 31 percent of all young singles in the sample were missing values for at least one source of income, but only 28 percent of single men were, compared with 35 percent of single women.[16]

In most of the analysis presented in this text, total outlays are used as a proxy for permanent income. However, in this section,

the purpose is to estimate total outlays while controlling for demographic differences, so that demographic subgroups can be compared. Clearly, current income (measured in the CE by income before taxes) is expected to be an important predictor of permanent income. Therefore, leaving it out of the right-hand side of the regression equation would cause omitted-variable bias. Yet, as noted, including an estimate of current income that is subject to nonresponse also will cause bias in regression parameters. The parameter estimate for income will be biased upward[17] and, especially given that income is correlated with other right-hand-side variables, may bias their parameter estimates in ways that are undeterminable a priori. Consequently, to solve this problem, a two-stage least squares procedure is performed. In the first stage, a regression is run using Box-Cox transformed observations only from nonmissing income reporters who re-

port no losses for income from any source.[18] The parameter estimates from this regression are then used to predict transformed current income for all young single adults, whether or not they reported a value. This predicted value is then utilized as an instrumental variable in the second stage of the regression. That is, total outlays are regressed on predicted current income and other characteristics in order to ascertain whether there is evidence to suggest that subgroups of young single adults have experienced an increase or a decrease in economic well-being as measured through predicted permanent income.

Most of the independent variables used to predict current income are the same as those used to predict total outlays. However, some variables are excluded from this model, while others are included. The numbers of automobiles and other vehicles are excluded from the income model because their importance in predicting income is not apparent a priori. Instead, added to the model are several variables describing the type of income received, such as income from investment sources (interest, dividends, rental income, other property income, or pensions and an-

nuities). Most of these categories are taken from those published in standard CE tables, but there are some modifications. The category "Social Security, private and government retirement" is not included in the table. Instead, its components are moved to other categories. Social Security, for example, is moved to "public assistance, supplemental security income, and food stamps" because young adults are not eligible for Social Security, except in cases of disability or survivors' benefits. The component for pensions and annuities is included with interest, dividends, and rental and other property income to form "investment income," because it is likely that anyone in this age group who correctly reports having received that type of income is receiving income from investment in an annuity, rather than pension income. Finally, these categories include only money income, so meals and rent as pay are excluded from "other" income.

Table A-3 shows the regression results utilized to predict current income, which is the variable used in the second stage of the two-stage least squares procedure. Table A-4 shows the results of the second-stage analysis, in which real total outlays are predicted.

Notes to the appendix

[1] In general, the Consumer Expenditure Survey (CE) collects information on expenditures made, but not on amounts or quantities purchased. For example, a person may report having spent $20 for movie tickets in the past 3 months, but data on whether that person went to the movies twice and spent $10 each time or went 10 times to a discount movie theater are not collected.

[2] Note that similar comparisons can be made even when neither period of interest is the base year for the index. For example, suppose that the analyst wants to compare expenditures that took place before the base year with those in the second period. Suppose also that the price index for the pre-base-year period in question is 80.0 and the expenditures for that period are $3. To convert these expenditures to second-period values, the analyst once again multiplies the expenditures from the pre-base-year period by the ratio of the second-period index to the index for the pre-base-year period (that is, [400.0/80.0] × $3 = $15). The result shows that real expenditures in the pre-base-year period are less than the value of expenditures reported in the second period. Therefore, the purchaser must have purchased more pounds of apples in the second period than in the pre-base-year period, even though the price of apples has increased.

[3] These comments pertain to the Laspeyres index, upon which the Consumer Price Index (CPI) is based. (See BLS *Handbook of Methods* (Bureau of Labor Statistics, June 2007), Chapter 17, "The Consumer Price Index," especially p. 3, on the Internet at **www.bls.gov/opub/hom/pdf/homch17.pdf** (visited Mar. 25, 2008).) Although other price indexes exist that attempt to adjust for these kinds of substitutions, a complete discussion is beyond the scope of this article.

[4] The food-at-home figure is computed by comparing the value in the final year of interest with the value in the first year of interest and computing the percentage by which expenditures would have to increase each year to reach the value in the final year. The formula is described subsequently in this section of the appendix.

[5] For all consumer units, average annual expenditures reported in the Diary Survey for food at home excluding food prepared by the consumer unit on out-of-town trips increased by 1.8 percent from 1987 to 1988; at the same time, these expenditures increased by 16.2 percent according to results from the Interview Survey.

[6] F statistic = 0.16; p-value = 0.6977.

[7] The adjusted mean for grocery store expenditures rises a modest 3.4 per-

cent during this period. The mean for expenditures at other stores rises 21.1 percent from 1987 to 1988 after adjustment, but this percent change is not out of line with figures for other years. The largest percent change, from 1995 to 1996, is 28.0 percent.

[14] For a brief description of methods used prior to 1972–73, see Geoffrey D. Paulin and David L. Ferraro, "Imputing income in the Consumer Expenditure Survey," *Monthly Labor Review*, December 1994, pp. 23–31, especially pp. 23–24; on the Internet at **www.bls.gov/opub/mlr/1994/12/art3full.pdf**.

[15] *Ibid.*; page 31 gives an example of how nonrandom nonresponse affects the mean for income.

[16] Interestingly, in 1984–85, there was greater similarity in reporting: 13 percent of young singles (12 percent of men and 15 percent of women) were missing at least one income value. Nonetheless, the p-value for the chi-square statistic of the (unweighted) sample is 0.065, indicating that the results are statistically significant at the 10-percent level.

[17] This claim is based on the assumption that most missing income is positive; therefore, total outlays for a consumer unit with missing income will correspond to a smaller income than the consumer unit actually receives. For some sources, such as self-employment or rental income, it is possible to report a loss. If the amount is missing, however, then the reported income associated with total outlays will be larger than the income the consumer unit actually received. However, losses are reported infrequently, so the assumption that missing incomes are positive is expected to hold in most cases.

[18] Losses can occur for self-employment and property sources of income. However, the Box-Cox transformation does not accept losses in those cases, because the value for λ (3/8) is an even number. The even root (for example, the square root, or the eighth root elevated to the third power in this case) does not exist for negative numbers. Although, for total income before taxes, losses of components of income can be offset by other values (for instance, a $500 loss is offset by a $2,000 wage or salary), income losses even in these cases are infrequent, will serve mainly to increase the variance of predicted income, and may bias the parameters used to predict income. Because the purpose of the regression is to obtain reasonable predicted values for use in the second stage, rather than to provide precise measures of relationships between outlays and actual income, it is reasonable to use the most typical cases (that is, those without losses) as observations for the first-stage regression.

Business Processes and Business Functions: a new way of looking at employment

A new BLS classification system used in conjunction with the Agency's Mass Layoff Statistics program yields fresh information on business processes and functions affected by mass layoff events

Sharon P. Brown

When employers decide to add or eliminate jobs, they are sometimes guided by larger choices to add or eliminate entire classes of activity—business functions—within the company. What may appear to be incremental hiring may in fact be the gradual buildup of a new business function, such as an in-house information technology development department. Or, instead, a mass layoff may stem from a decision to outsource a specific business function, such as human resources management, logistics, janitorial maintenance, or even manufacturing. Deciding which business functions to source to outside vendors and which to perform in-house is a critical part of corporate strategy, as companies seek to become more efficient and competitive or address changes in demand for outputs or supply of inputs.

In an attempt to shed more light on how workplaces and industries are changing, a classification system has been developed that describes basic business processes of the firm and the business functions that are associated with them. This system is now being used in the Mass Layoff Statistics (MLS) program to identify the functions and processes involved in job losses from extended mass layoffs. The system, which is now providing new information on the nature of this type of change in establishments and industries, can be applied equally to other measures of employment,

including the current employment structure of a firm, organizational expansions and job growth, and the geographic location of outsourced work. Called Business Processes and Business Functions, the system is based on an approach that is a synthesis derived from existing literature, models of firms' activities, current research on outsourcing and offshoring, the results of a feasibility study of business functions conducted by the BLS MLS program, and the ongoing collection of the relevant information throughout the Nation by the program.

Movement of work statistics

Restructuring and outsourcing of business functions has long been part of the U.S. economic landscape. Companies continually identify strategies to cut costs, become more efficient, expand, and gain access to new markets, among other motivations. As the horizons for moving work have expanded, the offshoring of jobs has become an option that is available to a growing number of employers. Offshoring is often thought to affect only, or at least mainly, manufacturing jobs and production functions. In the early 2000s, however, job losses in information technology and related areas emerged as an important indicator of ongoing change in industries. By 2004, stories on the offshoring of these business functions and the resultant

Sharon P. Brown is Chief, Division of Local Area Unemployment Statistics, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics. E-mail: brown.sharon@bls.gov

job losses in the United States had become a regular topic of debate in the popular media.[1]

As greater attention was placed on a firm's decision to outsource activities, stories also continued about corporate reorganizations and restructurings. These actions were occurring essentially for the same reasons that firms outsource and also involved processes and functions within the company. Companies were consolidating activities, eliminating layers of management, outsourcing some functions, and expanding others internally, to become more efficient and competitive and thereby improve the corporate bottom line.

In order to quantify the anecdotal information on offshoring and outsourcing, the BLS focused on the MLS program, in which monthly and quarterly statistics are collected on plant closings and mass layoffs involving at least 50 workers from businesses employing 50 or more.[2] A set of questions on the movement of work was added to the MLS employer interview to obtain the following data:

- *Job loss associated with outsourcing.* The movement of work to a different company when that work was formerly conducted in-house by employees paid directly by the outsourcing company. The different company can be located inside or outside of the United States. The work may occur at a geographic location different from that of the outsourcing company, or it may remain on-site.

- *Job loss associated with offshoring.* The movement of work from within the United States to a location outside of the Nation. Offshoring can occur either within the same company, when it involves the movement of work to a different location of that company outside of the United States, or to a different company altogether (called *offshoring/outsourcing*).

Statistics on outsourcing and offshoring have been collected by the MLS program since 2004. Job losses associated with the movement of work outside of the United States and that took place for reasons other than seasonal or vacation-related reasons averaged about 2.3 percent of all private nonfarm separations identified by the MLS program over the period 2004–07. Contrary to expectations, job losses associated with the movement of work were not concentrated in industries directly connected to computer and electronic products or information. Also, the majority of this layoff activity was associated with domestic relocation of work, mostly within the company.

If media reporting on offshoring correctly identified an emerging economic phenomenon, one implication of the MLS statistics on offshoring job losses was that the action involved an activity or function *not* directly associated with the industry designation of the firm. That is, information technology jobs were being moved out of the country, but from firms with other industry designations. An additional impetus for studying business functions came from the high level of activity in domestic relocations. The single most reported reason for these relocations was reorganization within the company. Despite the details collected on the layoff, the employer interview questions did not reveal what was behind these actions and what, in fact, was the affected part of the company.

The traditional classification schemes for identifying industries (the North American Industrial Classification System, or NAICS) and for defining occupations (the Standard Occupational Classification system) are not reflective of the full range of activities of the firm. The industry classification approach is based on the primary activity of the establishment, as measured by the largest number of jobs performing that activity; other important direct and support activities that operate within the firm are not explicitly recognized. Hence, any change in employment is associated with the industry code determined by the main activity, even if the change in activity has nothing to do with it. Looking at the occupational classification reveals that the problem is that the system defines the firm's workers, but lacks a direct tie to the firm's internal organization and decisionmaking. Thus, both industry and occupation provide a limited picture of the dynamic nature of industrial organization and economic change.

As it became clear that companies were using internal organizational schemes in analyzing and implementing employment change that could—and did—involve any part of the corporate structure, a new classification system reflecting these components was needed in order to better understand the nature of changes in employment.

Describing a firm's activities

Although Federal statistical programs have not collected statistics on business processes or functions, such data have been used in economic studies and, in recent years, have been mentioned in the popular press in stories on globalization, offshoring, and firm restructuring. Academic economists have described a firm's activities theoretically and used the concept of business organization in firm and industry studies. Among such approaches is Michael Porter's *value chain*, which divides a company's technologically and economically distinct activities that it performs to do business into primary activities and support activities.[3] Similarly, George

Yip has described the impact of global competition and technological improvements on the organization of firm activities and industries, and Timothy Sturgeon and Gary Gereffi, coorganizers of the Global Value Chains Initiative, have contributed to the discussion by identifying and distinguishing between core business processes and support activities, using an approach based on the classification scheme developed for the MLS program.[4]

Many offshoring studies and news accounts focused on activities such as software development and data processing, and relocations of call centers and customer services. One such report, prepared by Ursula Huws and Simone Dahlmann, described the following seven functions in which patterns of global outsourcing exist in the European Union: software development; data processing; sales; customer services; creative and content-generating functions, including research, development, and design; financial functions; and management, human resources, and training functions.[5] These functions could not be viewed solely as industries or occupations, because they can, and do, operate within any establishment, irrespective of its industry classification, and they involve a range of occupations. Not only were studies and news accounts discussing offshoring in terms of business functions, but new companies were being created to provide these outsourced functions to employers.

Business Processes and Business Functions

In order to provide a standard classification approach for use in the MLS program, a set of eight business processes was identified that defines the full range of activities a firm engages in to conduct its business. Within these processes are business functions that describe in greater detail the specific activity that a firm performs in order to produce its product, provide its service, or otherwise achieve its objective. The processes begin with the procurement of inputs and end with those services provided after the sale of the good or service. The eight processes are grouped into core business processes and support business processes. Core business processes relate most directly to the basic business of the firm, with operations representing the key industry activity of the company. Support business processes facilitate core business processes.

Core business processes.   Following are the five core business processes characterizing any firm:

- *Procurement, logistics, and distribution.* Those activities associated with obtaining and storing inputs,

and storing and transporting finished products to customers.

- *Operations.*   Those activities which transform inputs into final outputs, either goods or services.

- *Product or service development.*   Activities associated with bringing a new, improved, or redesigned product or service to market. Among these activities are research, marketing analysis, design, and engineering.

- *Marketing, sales, and customer accounts.*   Activities aimed at informing existing or potential buyers. These activities include promotion, advertising, telemarketing, selling, and retail management.

- *Customer and aftersales services.*   Support services provided to customers after they purchase the good or service. Such activities include training, help-desk services, call-center services, and customer support for guarantees and warranties.

Support business processes.   Three support business processes characterize a firm:

- *General management and firm infrastructure.* Corporate governance (legal, finance, planning, and public and government relations), accounting, building services, management, and administrative support.

- *Human resource management.* Activities associated with recruiting, hiring, training, compensating, and dismissing personnel.

- *Technology and process development.* Activities related to maintenance, automation, design or redesign of equipment, hardware, software, procedures, and technical knowledge.

The classification approach used in the MLS program differs slightly from the major models of a firm's activities defined by Porter, on the one hand, and Sturgeon and Gereffi, on the other. The MLS approach identifies *product or service development* as a core business process, whereas Porter includes it under support activities. Also, the MLS scheme includes *procurement* as a core business function, along with *logistics* and *distribution*. By contrast, in Porter's value chain, *procurement* is a separate support activity. As regards the Sturgeon-Gereffi model, *customer and aftersales service* is categorized as a support activity, whereas the BLS

scheme includes it as a core business process. Perhaps the most significant difference in the BLS and Sturgeon-Gereffi conceptual frameworks is the inclusion in the latter, but not the former, of *strategic management* as a core business process.[6] Although Sturgeon and Gereffi's categorization is undoubtedly correct, its relevance to the collection of job losses associated with mass layoffs and plant closings is questionable. Those individuals making up strategic management in a firm would most likely *not* be unemployed and, therefore, filing for unemployment insurance in the event of a layoff or closing—a necessary action for identification by the MLS program. Thus, although *strategic management* is a core business process for the company, it was not identified as a core business process in the BLS MLS approach.[7]

Exhibit 1 describes the full Business Processes and Business Functions system—including strategic management—with examples within each category. The functions are gathered from literature and from recent experience in collecting business functions in the MLS program and are not meant to be definitive or all inclusive. The term "business function" is distinct from both "industry" and "occupation" as a descriptor of the firm. For example, the business functions listed under the process *procurement, logistics, and distribution* include such activities as *buying, loading*, and *transporting*. These activities are not analogous to industry designations or occupations: within a function, there can be a number of different occupations and a range of skill levels.

To properly classify a business function by the higher level process, it is essential to consider the industry of the employer. Business functions that are performed in order to directly transform inputs into final outputs are classified under the business process *operations*, which, in most cases, corresponds to the production process that is the basis for the establishment's NAICS classification or the activity most directly associated with it. The specific business function (*producing goods of a certain type* or *providing services of a certain type*) depends on whether the establishment is classified as a goods-producing or service-producing establishment in NAICS. Examples of other business functions that are considered *operations* are the *direct supervision* of the activity, *fabricating*, and *assembling*.

It is important to note that a business function which falls into *operations* in one industry can be classified as a different business process in another industry. For example, let *accounting services* be the reported business function in an accounting firm. Then, in this case, the business process for the function is *operations*, because that activity directly relates to the service provided by the company. If, however, the function *accounting services* were reported by a manufacturing company, it would not be considered *op-*

erations, but would be classified under *general management and firm infrastructure*.

MLS feasibility study: business function collection

In advance of the development of the formal structure of the Business Processes and Business Functions system, the BLS conducted a feasibility study of business functions through the MLS program. The program collects important information on extended mass layoffs at large establishments through an interview with the affected employers. The interview includes 15 questions that address the nature of the layoff. For the feasibility study, an open-ended question about the business functions involved in the layoff or closing was added to the employer interview. Among the questions to be answered by this test were the following:

- Would an appropriate individual be found to respond to the business function question?

- Would that person understand the question and the concept of a business function?

- Would the responses be pertinent to business functions?

Ten States participated in the feasibility test as part of their regular MLS employer interview, asking the business function question for all layoff events identified in the State in September and October of 2006. Like regular MLS interviews, the test interviews were conducted by telephone and the employers were not given a copy of the interview questions with response options. Data on business functions involved in layoffs were collected through an open-ended question.

The sequence of the questions used in the interview was viewed as very important in ensuring that the discussion of the layoff event would lead to the concept of "business function." That is, the layoff or closing was verified, the economic reason for the layoff was provided, and the industry of the establishment was verified, leading to the question about business functions involved in the layoff. The interview questions and objectives leading to the business function question are shown in exhibit 2. (The full set of questions for the employer interview is presented in exhibit 3.)

Summary of major findings. The 10 participating States collected business function responses related to 154 extended mass layoff events reported for September and October 2006. In all, 237 business functions were reported.

Exhibit 1. **Classification of business processes with selected business functions**

Core business processes

Strategic management.   Those activities carried out at the highest managerial levels. Included are the formation, implementation, and evaluation of cross-functional decisions that enable the organization to achieve long-term objectives. Among such operations are the following:

Coordinating activities	Identifying new investments, acquistions, and divestments
Setting product strategy	

Procurement, logistics, and distribution.   Those activities associated with obtaining and storing inputs and with storing and transporting finished products to customers:

Buying	Shipping
Distributing	Receiving
Loading	Transporting
Packing	Warehousing

Operations.   Those activities which transform inputs into final outputs, either goods or services. In most cases, business functions categorized as operations will equate with the industry code of the establishment or the activity most directly associated with that code. The specific function—the production of a good or the provision of a service—will relate to the specific industry. Operations activities are as follows:

Assembling products	Managing production
Producing goods	Managing services
Providing services	Conducting quality assurance or quality control
Fabricating components	

Product or service development.   Activities such as the following, associated with bringing a new, improved, or redesigned product or service to market (many of these activities are research, marketing analysis, design, and engineering activities):

Developing business plans	Developing products or services
Analyzing markets	Researching products or services
Designing products or services	Testing

Marketing, sales, and customer accounts. Activities aimed at informing existing or potential buyers (many of these activities are promotion, advertising, telemarketing, selling, and retail management activities):

Advertising	Conducting market research
Managing accounts	Coordinating media relations
Billing	Merchandizing
Branding or managing products	Processing orders
Collecting payments	Selling
Marketing	Telemarketing

Customer and aftersales service.   Activities, including training, help desks, call centers, and customer support for guarantees and warranties, that provide support services to customers after purchase of the good or service:

Offering call center services	Maintaining and repairing products
Providing customer relations	Providing technical support
Providing customer service or support	Providing warranty support
Installing products	

Support business processes

General management and firm infrastructure.   Corporate governance (legal, finance, planning, and public and government relations), accounting, building services, management, and administrative support activities:

Accounting	Managing fraud
Providing administrative support	Providing general management
Providing cafeteria services	Managing government relations
Providing clerical support	Providing housekeeping services
Managing contracts	Providing investor relations

Exhibit 1.	Continued—Classification of business processes with selected business functions

Managing documents
Providing facility or maintenance services
Managing finances

Providing legal and regulatory support
Planning
Maintaining security

Human resources management.   Activities associated with recruiting, hiring, training, compensating, and dismissing personnel:

Providing employee assistance
Managing human resources
Offering labor relations services
Managing payroll and compensation

Hiring and firing personnel
Recruiting
Training

Technology and process development.   Activities related to maintenance, automation, design or redesign of equipment, hardware, software, procedures, and technical knowledge:

Developing computer systems
Maintaining or repairing computer systems
Managing data
Processing data
Engineering

Providing Internet services
Designing processes
Developing and testing software
Providing software and information technology
   services

The function most reported fell under the business process *operations*. This result was expected for the MLS program, because the program focuses on relatively large layoffs (50 or more workers) at relatively large firms (employing 50 or more), and the firm has the largest number of its workers involved in operations.

The new question on business functions worked well. The States reported little difficulty in finding a knowledgeable respondent. Relatively few respondents had difficulty answering the question, thus supporting the assumption that the concept of a business function had meaning and applicability for them. Most employers provided the names of one or more business functions in their immediate response to the question. The study did identify areas where clarification and guidance were needed. For example, it was necessary to ensure that information on *all* business functions involved in the layoff, and not just the main function, was collected. Also, during the test, probes were developed for use when the employer responded with occupations instead of business functions.

On the basis of the feasibility study results, the collection of data on business functions in the MLS program in all States began with mass layoffs and closings reported for the first quarter of 2007.

Functions and processes in the MLS program

Since the January 2007 implementation of the system, State analysts have collected data on business functions involved in extended mass layoffs (those lasting more than 30 days) as part of the employer interview, and since June 2007, they have coded those functions to higher level business processes. Analysis of the performance of the system over the first year indicates no significant issues on the part of either the employers interviewed or the data collectors. (See table 1.)

Asking employers about business functions has not adversely affected either the interview or the response rate. In 2007, a total of 14,046 employers were contacted because administrative data on unemployment insurance claims indicated that a layoff occurred. Extended layoffs and closings were identified for 5,364 private employers in nonfarm industries. Employers refused to participate in an interview in well below 5 percent of events. "Do not know" responses to the business function question remained low, indicating that the correct person is being reached for the interview and that most respondents in fact think in terms of business functions. The number of employers that the interviewer was unable to contact was relatively high and likely reflects total closure of the establishment by the time contact was made.

In order to preclude the analysts' influencing results by having them interpret the business functions cited by employers, responses are reported as stated. This approach results in variations in the words used to identify the business function. (As an example, the following terms were among those reported to describe construction activities: construction, constructing, road construction, construc-

Exhibit 2.

Exhibit 2. Selected Mass Layoff Statistics survey employer interview questions leading to business functions involved in the layoff event

Wording of question	Objective of question
1. **Based on our unemployment insurance claims records, we believe that you may have had a (layoff/reduction in staff) during (month). Is that true?** ☐ Yes ☐ Valid No (Probe: Do you know why these unemployment claims were filed against your company? Enter explanation. End interview.) ☐ Don't know (Ask for another contact) ☐ Refusal	To determine whether a layoff occurred at the establishment or worksite. (An example of a "valid no" is the filing of 50 or more initial claims throughout the State, but not all of them at the same worksite.)
2. a. **When did that layoff begin?** _____ b. **When did you stop laying off workers?** _____	For data-editing purposes, to obtain the dates that the employer started and stopped laying off workers in this event.
3. **Were workers laid off for more than 30 days?** ☐ Yes ☐ No	To establish whether the layoff meets the criterion of permanency—that is, an extended event. If so, then the analyst proceeds to ask further questions. If not, the interview ends.
4. **About how many workers were laid off for more than 30 days?** (Probe: If there is a big gap between the number of initial claims and the number of separations) *Number:* _____ ☐ Don't Know/INA[1]	To ascertain the number of workers affected (that is, separated). If the number is less than 50, then the event is out of the scope of the survey.
5. **What was the primary reason for the job cutbacks?** ☐ Don't Know/INA[1] *Primary:* _____ *Secondary:* _____	To obtain the primary economic reason(s) for the layoff and, if possible, any secondary reason(s).
6. **What kind of business is conducted at the worksite that experienced the layoffs?** (Probe: What product do you manufacture or what service do you provide at that location?) *Industry:* _____ ☐ Don't Know/INA[1]	To verify the NAICS code of the worksite.
7. **Regarding the workers who were laid off, what was their main role or function within the company? For example, were they in manufacturing, sales, personnel, computer support, or something else?** (Probe: In addition to [function mentioned], were any of the employees affected by the layoff involved in other activities of the firm, such as clerical support, warehousing, or sales?) *Main:* _____ *Other:* _____	To ascertain the business functions involved in the layoff, including the main function.

Cover these points in your introduction:
• Introduce yourself, and the office you are calling from.
• Explain why you are calling.
• Summarize key points of confidentiality pledge. If asked, give 1220–0141 as the OMB clearance number.
• Explain that this data collection is voluntary, and it will only take a few minutes

Question about the layoff

1. **Based on our unemployment insurance claims records, we believe that you may have had a (layoff/reduction in staff) during (month). Is that true?**
   ☐ Yes
   ☐ Valid No → (Probe: Do you know why these unemployment claims were filed against your company? Enter explanation. End interview.)
   ☐ Don't know → (Ask for another contact)
   ☐ Refusal

2. a. **When did that layoff begin?** _____
   b. **When did you stop laying off workers?** _____

3. **Were workers laid off for more than 30 days?**
   ☐ Yes
   ☐ No

4. **About how many workers were laid off for more than 30 days?** (Probe: If there is a big gap between the number of initial claims and the number of separations)
   Number: _____
   ☐ Don't Know/INA[1]

5. **What was the primary reason for the job cutbacks?**
   ☐ Don't Know/INA[1]
   Primary: _____
   Secondary: _____

6. **What kind of business is conducted at the worksite that experienced the layoffs?** (Probe: What product do you manufacture or what service do you provide at that location?)
   Industry: _____
   ☐ Don't Know/INA[1]

7. **Regarding the workers who were laid off, what was their main role or function within the company? For example, were they in manufacturing, sales, personnel, computer support, or something else?** (Probe: In addition to [function mentioned], were any of the employees affected by the layoff involved in other activities of the firm, such as clerical support, warehousing, or sales?)
   Main: _____
   Other: _____

8. **In which county is the worksite located?**
   County: _____
   ☐ Layoffs occurred at more than one worksite and county

9. **Just prior to the layoff, what was the total number of employees at this worksite, counting both hourly and salaried workers (an estimate is okay)?**
   Number:
   ☐ Don't Know/INA[1]

See footnote at end of exhibit.

Exhibit 3. **Continued—Employer Interview script**

10. **During the cutbacks/layoff, has your worksite remained completely open, partially open, or has it shut down completely?**
    - ☐ Open, no change in operating status
    - ☐ Open, divisions stopped or shifts cut
    - ☐ Partial closure of single-unit establishment
    - ☐ Closed, entire worksite(s)
    - ☐ Closed, entire establishment
    - ☐ Long-term work completed offsite
    - ☐ Don't know/INA

11. **Will there be a recall of workers, and, if so, what percent will return to work?**
    - ☐ Yes, enter percent: ———— (and check box)
      - ☐ 100%
      - ☐ 50–99%
      - ☐ Up to 50%
      - ☐ Don't know
    - ☐ No → Skip to Question 13
    - ☐ Don't know (ask for another contact) → 13

12. **What is the anticipated return date for those who were separated?**

    Date: ———————— (and enter range)
    - ☐ Less than 90 days
    - ☐ 90–180 days
    - ☐ 181–270 days
    - ☐ 271–364 days
    - ☐ 365 or more days
    - ☐ Don't know/ INA[1]

Questions about Movement of Work

Do not ask Questions 13–14, if:
- Reason for layoff was seasonal or vacation
- Layoff was temporary (30 days or less)

13. a. **Did this layoff include moving work from this worksite to a different geographic location within your company?**
    - ☐ Yes → Ask 13b
    - ☐ No → Go to 14a
    - ☐ Don't know → Go to 14a

    b. **Is the other location inside or outside the U.S.?**
    - ☐ Don't know/INA[1]
    - ☐ Inside U. S. → In what State(s)?
      ———————————————————————
    - ☐ Outside U.S. → In which country(ies)?
      ———————————————————————

c. **Of the total number of workers laid off, how many were laid off because your company moved work to this new location? (an estimate is okay)**

   Don't know/INA[1]

Number inside U.S. ————————————

Enter State(s) & No: ———————————————

Number outside U.S. ————————————

Enter Country(ies) & No: ——————————————

14. a. **Did this layoff include moving work that was conducted in-house by your employees to a different company, through contractual arrangement?**
    - ☐ Yes → Ask 14b
    - ☐ No → Go to 15
    - ☐ Don't know → Go to 15

    b. **Is that company located inside or outside of the U.S.?**

    Don't know/INA[1]
    Inside U. S. → In what State(s)?
    ———————————————————————
    Outside U.S. → In which country(ies)?
    ———————————————————————

    c. **Of the total number of workers laid off, how many were laid off because your company moved work to a different company? (an estimate is okay)**

    Don't know/INA[1]

Number inside U.S. ————————————

Enter State(s) & No: ———————————————

Number outside U.S. ————————————

Enter Country(ies) & No: ——————————————

15. **Thank you very much. Let me be sure I have all of your information correct just in case I need to get back to you at a later date. Can you tell me your name, job title, and phone number?**

Name: ———————————————————————

Job Title: ————————————————————

Direct telephone number: ———————————————

See footnote at end of exhibit.

Summary Information

Layoff Status (check one)

☐ *Temporary*: Layoff less than 31 days

☐ *Permanent/Extended*:   Layoff included at least 50 separations and lasted more than 30 days

☐ *Closure*: One or more worksites closed or entire establishment closed

☐ *No Layoff*: Employer indicates that there was no layoff or that separations were either voluntary (e.g., quits, retirements, transfers to other locations in company) or involuntary (e.g., firings due to employee misconduct, failure to perform duties).

tion activity, construction activities.) In the first quarter, 487 terms were used to report 1,862 business functions. Twenty-eight of those terms were used 10 or more times, accounting for 1,113 business functions, 60 percent of the total reported. (See table 2.)

Guidance was provided to analysts in an attempt to standardize terms for a number of functions and eliminate overly detailed functions. For the second through fourth quarters, about three-quarters of the business functions reported were associated with terms used 10 or more times.

The standardization effort focused on business func-

tions that frequently appear in a firm, such as administrative support, clerical support, construction activities, general management, food services, and lodging services. Exhibit 4 lists some standardized nomenclature for reported business functions. In some instances, the functions reported (for example, dishwashers and electricians) were overly detailed, approximating occupations. In industries such as construction, the activities reported were closely aligned to the industry. In providing guidance to the analysts conducting the employer interview, an attempt was made to standardize the level of detail and the reported activity where appropriate.

Table 1.	Total mass layoff events, selected measures, 2007, by quarter				
Action	First quarter	Second quarter	Third quarter	Fourth quarter
Total potential mass layoff events.......................................	3,139	3,289	3,025	4,593

Unable to contact	75	69	77	122

Exhibit 5 displays the business functions reported in extended layoff events for the third and fourth quarters of 2007 (as reported in early 2008), loosely grouped by business process and without regard to the industry of the establishment experiencing the layoff. As an example, functions that involve the provision of services are grouped together. From the business process perspective, and as previously described, it is important to recognize that any one of the listed business functions can represent either *operations* of the establishment (if the function directly represents the industry code) or a non-*operations* process. For example, the 30 business functions reported in the third quarter as *accounting services* may represent *operations* from accounting firms or *general management and firm infrastructure* if the accounting functions were associated with firms from other industries.

Fifty-five business functions are identified in the exhibit, based on functions specifically cited by employers and those which could easily be associated with the stated function. Out of 1,666 functions reported in the third quarter, 1,528 were grouped into these standard functions. For the 2,325 business functions reported in the fourth quarter, 2,075 were so categorized. Taking into account those instances in which the employer did not know the affected function, analysts were able to assign more than 90 percent of the reported functions to these standard functions each quarter.

About 25 percent of the 1,666 functions reported in the third quarter were associated with the production of goods and with construction activities. The provision of services accounted for nearly the same proportion of functions. Of interest during this quarter were reports of functions likely associated with the housing and mortgage downturn—that is, those involving *real estate, lending (including mortgage), financial, and banking services*. Also in this quarter were layoffs associated with *educational services*, as schools closed for the summer. Functions considered under the *procurement, logistics, and distribution* process accounted for about 12 percent of reported activity, with some of those grouped as *transporting* also reflecting school closings. In the fourth quarter, 28 percent of the

2,325 functions that were reported involved extended layoffs associated with *construction* functions, reflecting the seasonal slowdown in that activity. *Landscaping services* functions also were related to the time of year.

Identifying the business process

Business process identification involves categorizing the specific business function into one of the eight processes previously described and used in the MLS program. The first step is determining whether the business function is part of *operations* for the establishment. This key categorization hinges on the relationship of the function to the industry of the establishment. As previously described, in most cases, when a business function is identified as part of *operations,* it is because it corresponds to the production process that is the basis for the establishment's NAICS classification or to the activity most directly associated with that classification. The specific business function depends on whether the establishment is classified as a goods-producing or service-producing establishment in NAICS. (Other business functions, such as the direct management of the specific services or production, also are classified under *operations*.)

A business function that is classified under *operations* for one establishment can be correctly classified as a different business process for another establishment, depending on the industry of the establishment. The business function *warehousing* provides an example: if the job loss associated with this business function occurred in an establishment identified as a warehouse, then the process involved would fall under *operations*; however, if the function was reported by a manufacturing establishment, then the process involved was *procurement, logistics, and distribution*.

It is important to recognize that the MLS-identified establishment and its industry designation are from QCEW data used to administer the unemployment insurance program in a particular State. Industry classification is based on the majority (or plurality) of the work the firm reports that it performs in that State. In the case of firms with multiple establishments in the State, all locations will

Table 2.	Business function terms and responses, 2007				
Quarter	Unique business function terms		Business function terms with 10 or more responses	
	Number	Total business functions	Number	Total business functions
First..	487	1,862	28	1,113
Second...	302	2,350	33	1,815
Third...	218	1,666	30	1,307
Fourth...	288	2,445	35	1,977

NOTE: Table excludes responses of "don't know" and "is not available" to the business function question.

reflect the activity of the majority of employment in the State.

If the establishment identified by the MLS program as having a layoff event is part of a larger corporate entity located outside of the State and with an industry designation different from that of the establishment, then the business processes determined from the business functions that take place at the worksite will not relate to that larger corporate entity. An example is retail outlets of a manufacturing company. If the State has only the retail stores, and not the parent manufacturing firm, then layoffs at those stores involving the business function *selling* would be identified as *operations*, because the industry is retail sales. However, relating the business function to the industry of the larger corporate entity located in another State would place the function under the business process *marketing, sales, and customer accounts*. Thus, the MLS program may categorize an inflated number of business functions as *operations*, because the industry identification of the establishment may reflect neither the firm's position in the corporate structure nor corporate actions.

2007 analysis of MLS business processes

In 2007, the MLS program reported on 5,364 extended mass layoff events involving the separation of 966,526 workers.[8] During this period, the collection of data on business functions involved in layoffs was implemented, as was the coding of these functions to higher level business processes. As previously noted, the early collection was important not only for providing the initial, nationwide data on this activity, but also for identifying areas in which guidance was needed and automation would improve both collection and analysis. The discussion that follows focuses primarily on business processes because of

refinements that were made to business functions in the early stages of data collection in 2007.

In 2007, employers reported a total of 8,323 business functions involved in 5,364 layoff events. When multiple business functions were cited in responses, the employer was asked to identify the main business function, on the basis of the largest number of jobs lost. The business functions were assigned to 6,679 business processes. (See table 3.) A single business process can reflect multiple business functions involved in a layoff. Over the year, 67 percent of mass layoff events involved only one process, but that proportion may reflect collection issues that arose in the first quarter and may change as interviewers become more familiar with the concepts and situations that apply. Almost 21 percent of events involved between 2 and 5 business processes. On average, the typical layoff involved 1.4 business processes.

Core business processes dominated in the reporting of layoff activity. *Operations* accounted for the majority of processes involved in layoffs: sixty-seven percent of all processes reported, and 94 percent of the main process reported, reflected one or more business functions categorized as *operations*. This is not an unusual finding for a program that looks at relatively large layoff events. Also, significant shares of mass layoffs are due to seasonal reasons and contract completions, activities typically associated with business functions that would be categorized as *operations* for the affected firms.

In layoffs involving more than one business process, there was a greater likelihood that some business functions other than *operations* that were involved in the layoff would be categorized as support processes rather than core processes. Excluding the main business process associated with the layoff, over the year, 58 percent of business processes other than the main one of the layoff were support processes, with 41 percent involved with *general management and firm infrastructure* and 10 percent with *human*

resource management. Core processes other than *operations* also played significant roles as secondary processes in layoffs. Nineteen percent of secondary business processes were identified as *procurement, logistics, and distribution,* followed by *customer and aftersales* service (9 percent) and *marketing, sales, and account management* (9 percent).

Open and closed status. During the January-December period, nearly 72 percent of the 4,745 layoff events reported no change in the worksite status, while 5 percent of the events involved full closure of the employer (without regard to recall expectations). Partial closures (for example, closures of worksites, divisions, or shifts) accounted for 22 percent of the events.

When the worksite status was not affected by the layoff, the distribution of main business processes involved was virtually identical to the total layoff distribution, with *operations* dominating. When worksites closed, the representation of support processes and of core processes other than *operations* rose significantly.

Industry distribution of extended layoffs. During 2007, manufacturing industries accounted for 25 percent of private nonfarm layoff events and separations. The largest concentrations were in transportation equipment and food manufacturing, followed by computer and electrical products. As regards nonmanufacturing sectors, 25 percent of all events were from construction, involving 16 percent of all separations over the period. Other signifi-

cant contributors to layoff activity included the retail trade and transportation and warehousing.

Among manufacturing industries, *operations* was reported to be the main business process for 95 percent of layoff events, about the same percentage as in all industries. However, these industries had a greater-than-average representation of secondary processes involved in the layoff. They also reported higher proportions of processes identified as *procurement, logistics, and distribution* and *product development,* as well as *human resource management* and *technology and process development,* than the proportion for all reported layoff events. (See tables 4 and 5.)

Both wholesale and retail trade reported lower proportions of events with *operations* as the main business process, but higher proportions with *marketing, sales, and account management.* The wholesale and retail sectors also reported high representations of secondary business processes, especially in *procurement, logistics, and distribution* and in *marketing, sales, and account management.*

As with most events, layoffs in the transportation and warehousing sector involved *operations* as the main business process. This sector had relatively higher representations of secondary support processes involved with *general management and firm infrastructure* and with *human resource management.*

In finance and insurance, the proportion of events in which *operations* was identified as the main business process was only slightly below that of all layoffs. With regard

---

to secondary processes involved in the layoff, of all industry groups, the finance and insurance sector had higher-than-average reporting of *marketing, sales, and account management* (along with wholesale trade and arts, entertainment, and recreation) and *customer and aftersales service.*

Economic reasons for layoff. Among the seven categories of economic reasons for a layoff, seasonal reasons accounted for 35 percent of the 5,364 layoff events and 364,225 separations over 2007. Business demand reasons followed, with 35 percent of events and 248,055 affected workers. Job losses associated with financial issues (bankruptcy, cost

control or cost cutting, or financial difficulty) accounted for nearly 9 percent of events and 102,362 separations. Organizational changes (business ownership change and reorganization or restructuring) were cited in more than 7 percent of events, involving 124,175 workers. Reorganization or restructuring accounted for the majority of these events, but business ownership change involved the majority of the separations.

Although the average layoff event involved 1.4 business processes, layoffs associated with organizational changes and financial reasons reported 2 or more processes involved. Layoffs due to these reasons were more

Table 3. Total, main, and secondary business processes involved in extended mass layoffs, 2007

Business processes in Mass Layoff Statistics layoff events	Total	Main	Secondary
Total business processes identified......................................	6,679	4,745	1,934

likely to report secondary support processes affected. In fact, other than the small number of events associated with disaster and safety, the highest proportions of *human resource management* as secondary support processes were associated with organizational changes and financial reasons. Business ownership changes were less likely to involve *operations* as the main process and more likely to involve a secondary support process, particularly *human resource management*. (See tables 6 and 7.)

Movement of work.   Movement of work accounted for 8 percent of the 3,484 extended mass layoff events (excluding those which took place for reasons other than seasonal or vacation-related reasons) and 8 percent of the associated separations. Of the 4,745 extended layoff events for which business functions were provided, 264 involved the movement of work; these 264 events involved the movement of work to other U.S. locations or to locations outside of the United States, and the movement occurred either within the same company or to other companies. A large majority (88 percent) of these actions involved moving work within the company, and most (71 percent) were domestic relocations.

When layoffs were associated with the domestic relocation of work, *operations* was cited as the main business process in 87 percent of events, compared with 94 percent when work left the United States. Secondary business processes involved when work was geographically relocated were heavily weighted toward support processes. For relocations within the United States, *general management and firm infrastructure* accounted for 41 percent of secondary processes reported in domestic relocations, followed by *procurement, logistics, and distribution* (19 percent) and *human resource management* (16 percent). Proportions for out-of-country moves were similar.

Operations was the main business process cited when work moved within the company (91 percent of events) and when work was moved to another company (84 percent of events). Secondary business processes were concentrated in support processes for both internal company moves and moves to another company and were generally similar.

THE CLASSIFICATION APPROACH of the BLS Business Processes and Business Functions system is a viable way of describing the establishment and its employment. The development and use of standardized business functions points to the greater potential of analyzing economic events at this detailed level. Despite the limitations imposed by the first year of data collection, the Business Processes and Business Functions system applied to extended mass layoffs provides interesting and timely insights into firms' decisions and how they are reflected in plant-closing and mass layoff data.   □

Service-providing occupations, offshoring, and the labor market

A BLS analysis identifies 160 service-providing occupations that are susceptible to offshoring; these occupations are diverse in their job functions, associated educational attainment, and wages

Roger J. Moncarz,
Michael G. Wolf,
and
Benjamin Wright

The Bureau of Labor Statistics (BLS) researches trends affecting the labor market as part of its Employment Projections Program. Although the BLS examines all factors affecting employment in industries and occupations, it pays particular attention to new or emerging topics. One such topic is the offshoring of service-providing occupations.[1] In recent years, special efforts have been made to identify the occupations that may be susceptible to offshoring and to account for offshoring in occupational employment projections. This article, representing the culmination of those efforts, identifies 160 occupations considered susceptible to offshoring and reports trends in historical and projected data for those occupations.

For most of recorded history, the majority of goods and services were produced and consumed locally. Developments in transportation—most notably, the locomotive and steamship and, later, the airplane and truck—made the large-scale remote production of goods practical. The result was a rapid increase in the trade of goods, causing manufacturers to face competition from abroad. Recent advances in telecommunications—in particular, the Internet—have enabled information to travel around the globe nearly instantaneously. Consequently, many

services that previously needed to be performed domestically now theoretically can be performed anywhere in the world. The movement of work that results from this development, generally termed "offshoring," has the potential to affect U.S. employment, but the nature and scale of its impact remain unclear.

As is common with new phenomena, the terminology used to describe offshoring is not always consistent. It is, therefore, beneficial to clearly define the issue. A report by the National Academy of Public Administration defines offshoring as "U.S. firms shifting service and manufacturing activities abroad to unaffiliated firms or their own affiliates."[2] That definition is consistent with the concept of offshoring identified in the analysis which follows. However, for several reasons, this analysis focuses only on the offshoring of services. First, the offshoring of manufacturing establishments has been occurring for a much longer period and is relatively clearly understood. Second, the factors that lead services to be susceptible to offshoring are different from those affecting manufacturing. Third, few data sources exist that provide insight into the occupations that are affected by services offshoring. These three reasons combined support an independent analysis of the offshoring of services.

Roger J. Moncarz is Branch Chief, and Michael G. Wolf and Benjamin Wright are economists, in the Occupational Outlook Studies Branch, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics. E-mail: moncarz.roger@bls.gov, wolf.michael@bls.gov, or wright.benjamin@bls.gov

It is important to note that this article addresses only the movement of work from the United States to other countries; occupations that may be affected by flows in the other direction—a movement known as "in-shoring"—are not identified. In general, occupations that are susceptible to being offshored are not necessarily the same as those which may be affected by in-shoring.

Current measures of services offshoring are limited by a dearth of relevant data. Perhaps the most useful indicator is the international trade data from the Bureau of Economic Analysis (BEA). Over the last two decades, these data show a large increase in international trade in both goods and services. In 1986, goods exports were $229.2 billion, while goods imports were $401.8 billion. By 2006, quantities had more than quadrupled, to $928.7 billion and $1.65 trillion, respectively. In 1986, service exports were $128.9 billion, while service imports were $110.7 billion. By 2006, service exports had nearly tripled, to $386.3 billion, while service imports more than doubled, reaching $283.7 billion.[3] It is noteworthy that, although the U.S. economy has been running an overall trade deficit for decades, there has been a consistent surplus in international services trade.

Measures of the value of international trade, however, cannot be used to gauge the scope of offshoring. An increasing surplus in services trade, for example, does not necessarily indicate a change in the level of offshoring in service occupations. In addition, the value of services trade usually is difficult to measure. This situation stems from the fact that goods, as opposed to services, are easier to measure and dominated international trade when the data collection systems were established.[4] In addition, goods are typically traded through a port of entry and are tracked relatively easily. Services, by contrast, are traded through diverse channels, many of which are difficult to observe.

A number of organizations, including Forrester Research, McKinsey Global Institute, Deloitte and Touche, and Goldman Sachs, have published studies trying to quantify the effects of offshoring on U.S. employment. Most of these studies predict that millions of jobs could be offshored over the coming years. Academic economists also have published studies estimating that millions of U.S. jobs are susceptible to offshoring.[5] All of these studies acknowledge the dearth of actionable data on the topic and are based on subjective assumptions.

The manner in which offshoring will affect U.S. employment is unclear. On the one hand, offshoring has the potential to reduce total U.S. employment if jobs are relocated to other nations. On the other hand, services exports may create new jobs within the United States and therefore raise total employment.[6] In addition, individual occupations are not likely to experience these effects uniformly, because some occupations are more susceptible to offshoring than others and some may face additional barriers to offshoring. If individuals lose their jobs in vulnerable occupations, they may need to obtain retraining before moving into another occupation. As a result, it is important to identify which occupations may be affected by offshoring.

Several studies have addressed services offshoring from an occupational perspective. Common among them is an attempt to identify the characteristics that make an occupation susceptible to offshoring. Ashok Bardhan and Cynthia Kroll, among the first to do so, concluded that offshorable occupations have "no face-to-face customer servicing requirement," "high information content," a "work process" that is "telecommutable and Internet enabled," a "high wage differential" with a "similar occupation" in the offshore destination, "low setup barriers," and a "low social networking requirement."[7] On the basis of these characteristics, and using the Standard Occupational Classification (SOC) system,[8] those authors identified 49 occupations as susceptible. The majority of these occupations fall into three SOC occupational groups: office and administrative support occupations, business and financial operations occupations, and computer and mathematical occupations. Bardhan and Kroll used data from the BLS Occupational Employment Statistics (OES) survey to estimate that these 49 occupations accounted for 14 million jobs, or 11 percent of total employment, in 2001. The authors limited their list to occupations that the business literature indicated were already being offshored at the time of their analysis, which may explain why the number of occupations identified in Bardhan and Kroll's study is lower than the number identified herein.

In an attempt to determine which jobs are able to be offshored, and the number of jobs that could be offshored, Alan Blinder created an occupational ranking system.[9] He stated that services which can be transmitted electronically with no reduction in quality can be offshored and all other services cannot. Most occupations, however, provide some services that can be transmitted electronically and some that must be delivered in person. Consequently, some occupations are more offshorable than others, creating an offshorability spectrum. Blinder's system, based on information from the Occupational Information Network (O*NET),[10] in addition to his own judgment, assigned each occupation a position in this spectrum. He then used the results to estimate that about 291 occupations are offshorable. Blinder based his occupational classifications on

the SOC system, but divided several occupations, resulting in additional occupations not included in the SOC system. He used data from the OES survey to estimate that these 291 occupations accounted for about 38 million jobs, or 29 percent of total employment, in 2004.

Blinder's analysis, however, is not directly comparable to the one presented here, because he included about 9 million jobs from production occupations and construction and extraction occupations, two SOC groups that are not considered service-providing groups. In addition, Blinder included residual occupations in his analysis. With the production occupations, construction and extraction occupations, and residual occupations removed to make the two analyses comparable, Blinder would find 152 occupations susceptible to offshoring; about 3 in 4 occupations that appear in his offshorability spectrum would appear here as well, with most of the disagreements occurring among occupations with lower susceptibilities to offshoring.

J. Bradford Jensen and Lori G. Kletzer responded to the previous subjective studies by creating an objective ranking system based on data on occupational characteristics developed by O*NET.[11] According to their analysis, the characteristics that increase susceptibility to offshoring are "getting information," "processing information," "analyzing data or information," "documenting/recording information," and "interacting with computers." The characteristics that decrease susceptibility are "assisting or caring for others," "performing or working directly with the public," "establishing or maintaining interpersonal relationships," "making decisions and solving problems," "thinking creatively," and "inspecting equipment, structures, or material."[12] O*NET attempts to quantify, through numeric ratings, the significance that each characteristic plays in each occupation. Using these ratings, Jensen and Kletzer assigned a score to each occupation and ranked occupations on the basis of that score. They then used the rankings to gauge how susceptible an occupation is to being offshored, thereby creating an offshorability spectrum of 457 SOC occupations.[13] There are some similarities between their spectrum and the list of occupations presented herein, with 131 of the occupations on the latter list appearing in the top half of Jensen and Kletzer's spectrum. There also are some large discrepancies, however, with several of the occupations with the highest levels of susceptibility on the list presented here appearing in the bottom half of Jensen and Kletzer's list.

The BLS Employment Projections Program has been studying the offshoring of service-providing occupations for the past decade, employing more than 20 economists who study occupations to make 10-year employment projections. Because offshoring is a factor that may affect future employment levels, BLS economists have researched the topic heavily and collectively have amassed a base of knowledge that covers the vast majority of occupations in the U.S. economy.[14] The study described in this article uses that knowledge to analyze the issue of offshoring.

The BLS offshoring scoring system

The BLS offshoring scoring system identifies characteristics that make an occupation susceptible to being offshored and ranks occupations by level of susceptibility. The system covers the 515 service-providing occupations listed in the SOC manual.[15] (See table 1.)

Many of these occupations, however, have no possibility of being susceptible to offshoring, rendering a detailed analysis of them unnecessary. The first step of the analysis, therefore, was to identify the occupations that had insurmountable barriers to offshoring. Most of these occupations either require face-to-face interaction with customers or require the work to be performed in a fixed location. (As examples, physical therapists and barbers belong in the first category, security guards and landscaping workers in the second.) Other occupations that were excluded due to insurmountable barriers were ones that perform intrinsically governmental functions, such as judges and correctional officers. After all occupations that were considered not at all susceptible were removed, the remaining 160 occupations were deemed susceptible to offshoring and were analyzed more closely. (See tables A–1 and A–2 for a full list of these occupations.)

BLS economists answered a series of questions regarding the characteristics of these 160 occupations. The questions were designed to measure each of the four characteristics that make an occupation susceptible to offshoring: inputs and outputs that can travel easily across long distances, such as electronically over the Internet; work that requires little interaction with other types of workers; work that requires little knowledge of the social or cultural idiosyncrasies of the target market; and work that is routine in nature. (See exhibit 1.) For each occupation, all four questions were answered by the economist who specializes in that occupation.

In order for an occupation to be offshored, the services that the worker provides must be able to travel across international borders. The more efficiently this can be done, the easier and more beneficial offshoring becomes. Work in which the main product is information or digital com-

Table 1.	Service-providing occupational groups

NOTE: Occupational groups exclude residual occupations not included in the analysis.

munication can be offshored more readily than work that may occasionally involve face-to-face communication or products that are not as easily transportable. (Mathematicians and telemarketers are examples of the first category, while sales representatives are an example of the second.)

High levels of interaction across an organization's departments can make an occupation difficult to offshore. Logistical problems can arise when such interaction takes place over long distances or across time zones, reducing the benefits of offshoring. General operations managers, for example, must maintain contact with all branches of an organization. Computer programmers, by contrast, can perform their duties with little to no interaction with those in other parts of an organization.

If the duties of an occupation require familiarity with the cultural or social idiosyncrasies of the target market—the kind of knowledge that can be obtained only by living in that market—performing those duties from abroad would be difficult. Marketing managers, for example, must understand the tastes of the population to whom they market their products. Tax preparers, however, need only know tax laws and a client's financial information, both of which can be obtained from places across the globe.

Work that can be routinized or handled by following a script is more susceptible to offshoring because the outputs, as well as the processes by which they should be completed, are easier to define. With such occupations, it is easier for companies to gauge whether the work is being completed, and less management oversight is needed. By contrast, work that is more creative is more difficult to monitor, making companies less likely to have it performed from remote locations. Nuclear engineers, for example, engage in detailed research and development, whereas insurance underwriters generally follow a set of instructions and are not part of an organization's creative functions.

The offshoring scoring system accounts for the degree to which each of the foregoing four characteristics influences an occupation. BLS economists were able to indicate whether each characteristic applied to an occupation to a very low degree, to a low degree, to a high degree, or to a very high degree. By not being limited to a simple binary response, the economists were better able to classify occupations that have a range of duties or specialties, some of which may be more susceptible to offshoring than others. The disadvantage of multiple options, of course, is the risk of inconsistency; to limit this risk, all scoring was reviewed by a team of

Exhibit 1.	Offshoring susceptibility questions, 2006–16				
1. To what degree can the inputs and outputs of the occupation be transmitted electronically, or otherwise be easily and cheaply transported?	Very low degree (1 point)	Low degree (2 points)	High degree (3 points)	Very high degree (4 points)
2. To what degree do the duties of this occupation require interaction with other types of workers?	Very low degree (4)	Low degree (3)	High degree (2)	Very high degree (1)
3. To what degree is knowledge of social and cultural idiosyncrasies, or other local knowledge, needed to carry out the tasks of this occupation?	Very low degree (4)	Low degree (3)	High degree (2)	Very high degree (1)
4. To what degree can the work of the occupation be routinized or handled by following a script?	Very low degree (1)	Low degree (2)	High degree (3)	Very high degree (4)

economists who had not done the original scoring, in order to ensure that different analysts applied the same standards.

After the questions were answered for all 160 occupations, the responses were used to generate a score for each occupation. Each question was worth a maximum of 4 points and a minimum of 1, with a 4 representing the greatest susceptibility to offshoring. As a result, the highest susceptibility score that an occupation could receive was 16, the lowest, 4. The scores were used to rank the occupations by susceptibility to offshoring.

On the basis of the distribution of the susceptibility scores, the 160 occupations were divided into three groups in order to compare occupations with similar degrees of susceptibility. Those with scores of 13–16 were grouped as the occupations with the highest susceptibility to offshoring, while those with scores of 4–7 were grouped as the occupations with the lowest susceptibility. Thirty-three occupations fell into the highest group, and another 33 fell into the lowest, with the remaining 94 falling into the middle group. (See tables A–1 and A–2.)

It is important to note that the questions posed in the scoring system are based strictly on an occupation's characteristics; thus, the rankings they generate are only a measure of the degree to which the duties of these occupations can be performed from a remote location. They indicate nothing about the likelihood, scale, or any other measure of offshoring. Occupations that exhibit similar levels of susceptibility do not necessarily have the same risk of being offshored.

For example, tax preparers and physicists are 2 occupations that score among the top 33 on the basis of occupational characteristics, but other factors significantly limit the extent to which these occupations actually may be moved offshore. Electronic documents and electronic filing allow tax preparers to be located almost anywhere in the world, but these developments, along with new software, also allow individuals to do their own taxes more easily. This factor may reduce the demand for these workers, as well as the likelihood that they will be moved offshore. Physicists, by contrast, face other restrictions to offshoring, including the fact that many physicists are employed by, or receive significant funding from, the Federal Government—funding that would not be available to them overseas.

The offshoring analysis system was initially created to account for an emerging trend in a systematic manner. After the development of the 2006–16 employment projections, the project was expanded to address a broader range of goals. In addition to improving the accuracy of the projections, it was determined that the results would be used to contribute to the publicly available information on offshoring, a topic of concern for many individuals, groups, and organizations. The occupational rankings can provide further insight into the topic, one that is still largely misunderstood and difficult to measure. In addition, detailed data are presented here on individual occupations, as well as on the offshorable occupations as a whole. Offshoring is only one of many factors that can affect occupations. No attempt should be made to attribute growth rates in an occupation, or differences between occupations, to offshoring.

Data

Occupational employment and wage data for the 2001–07 period come from the OES survey, which collects data on 801 detailed SOC occupations, including all of the 160 service-providing occupations analyzed in this article. An establishment-based instrument, the OES survey provides estimates on employment and wages for wage and salary workers in nonfarm establishments, but does not provide estimates for self-employed workers.

The OES data presented in this study span the years 2001–07, starting with the first year of data available on the 2000 SOC system.[16] Although 2007 data are available for all occupations, changes in survey methodology since 2001 do not allow for historical comparisons for 19 occupations. Therefore, rates of change for employment and wages in these occupations were not included in this analysis.

The analysis also presents several other data series from the Employment Projections Program, including the 2006–16 employment projection for each of the occupations deemed susceptible to offshoring. In addition, educational attainment data are presented to provide further demographic information. In an effort to reflect current educational needs, the analysis examines the educational attainment of younger workers—the percentage of 25- to 44-year-olds working in the occupation who have a high school diploma or less, some college or an associate's degree, or a college diploma (a bachelor's degree) or higher.[17]

Tables 2 and 3 present summary figures for these data series, and tables A–1 and A–2 contain detailed data on each of the 160 susceptible occupations. In addition, for comparison purposes, data also are presented on all service-providing occupations aggregated together. (See table 1.) Note that, although comparison against a benchmark provides some context for the data on offshorable occupations, differences should not be ascribed to offshoring; many other factors also are in play that will cause differences between sets of occupations.

Overall results

The offshorable occupations are quite diverse in their job functions, educational attainment, and wages. More than half of the 160 offshorable occupations are classified as professional and related occupations, a classification that includes a variety of professional and technical occupations. Particularly noteworthy is that almost every computer and mathematical science occupation has some degree of susceptibility to offshoring. One of the reasons that,

Table 2.	Average annual percent change in employment and earnings of susceptible occupational categories, 2001–07		
Susceptible occupational categories	Number of occupations	Average annual percent change in employment	Average annual percent change in earnings
All service-providing occupations	515	1.3	3.1
All offshorable occupations.....	160	1.5	3.6
Highest ranked occupations.	33	.4	2.8
Middle ranked occupations ..	94	2.2	3.7
Lowest ranked occupations ..	33	1.8	3.4

SOURCE: Occupational Employment Statistics (OES). Table excludes data for occupations in SOC 11–0000 (management occupations) and for five additional occupations for which 2001 data are not available.

for example, computer specialists are susceptible to being offshored is the ease with which computer programs and services can be transmitted electronically. There are also 27 office and administrative support occupations on the list. Fourteen managerial occupations appear on the list as well, although most of them are classified as occupations least susceptible to being offshored.

As a group, these 160 occupations accounted for about 30 million jobs in 2007, more than one-fifth of total employment. (See table 3.) The occupations grew at an average annual rate of 1.5 percent from 2001 to 2007, faster than the 1.3-percent rate for all service-providing occupations. Furthermore, the 160 offshorable occupations are projected to continue to grow faster than all service-providing occupations from 2006 to 2016, at an average annual rate of 1.2 percent, compared with 1.1 percent for the latter occupations. Wages in the offshorable occupations grew by 3.6 percent per year from 2001 to 2007, also faster than the 3.1-percent annual growth for all service-providing occupations. The 2007 mean annual wages of $61,473 in the offshorable occupations were significantly higher than the 2007 mean wages of $41,610 for all service-providing occupations. Fifty-four percent of the workers in the offshorable occupations possessed a bachelor's or higher degree, and more than 80 percent had at least some college education. These numbers, again, are higher than those for all service-providing occupations, in which 37 percent of workers had a bachelor's or higher degree and another 31 percent had some college education.

Highest ranked. The 33 occupations most susceptible to offshoring accounted for 9.5 million jobs in 2007. (See table 3.) The characteristics of these occupations reflect a wide range of skills and education. Fifteen are office and

administrative support occupations, with relatively low education or training requirements. Another 11 are professional and related occupations, which generally possess higher educational requirements. No management occupations are found in this group.

Wage and salary employment of the occupations most susceptible to offshoring grew slowly, just 0.4 percent per year from 2001 to 2007. (See table 2.) This rate of growth was significantly lower than the 1.3 percent exhibited by all service-providing occupations over the period. As a group, these 33 occupations are projected to grow by 1.1 percent per year from 2006 to 2016, equivalent to the projection for all service-providing occupations. (See table 3.) Individually, 20 of the 33 occupations most susceptible to offshoring are expected to experience employment growth, while 13 are expected to decline.

Mean annual wages for the most susceptible occupations were $38,201 in 2007, compared with $41,610 for all service-providing occupations. Wages for the most susceptible occupations grew more slowly (2.8 percent per year) than wages for all service-providing occupations (3.1 percent). The educational attainment of workers in the most susceptible group also was relatively low, with about 30 percent holding a bachelor's or higher degree, compared with 37 percent for all service-providing occupations.

Middle ranked. The 94 occupations that scored in the middle range of the offshoring analysis accounted for 14.3 million jobs in 2007. (See table 3.) The makeup of these occupations reflects the wide range of service-providing occupations that are susceptible to offshoring, but is weighted toward the more highly skilled occupations. Sixty-two of these occupations are professional and related occupations, and 12 are management, business, and

financial occupations. Among the professional and related occupations are sizable numbers of architecture and engineering occupations; life, physical, and social science occupations; and computer and mathematical science occupations. Other occupational groups that are well represented include arts, design, entertainment, sports, and media occupations, as well as office and administrative support occupations.

Wage and salary employment in the middle-ranked occupations grew by 2.2 percent per year from 2001 to 2007, much faster than the 1.3-percent growth rate for all service-providing occupations. (See table 2.) The middle-ranked occupations are projected to grow by 1.3 percent per year over the 2006–16 period, compared with 1.1 percent for all service-providing occupations. Ninety of the middle-ranked occupations are projected to grow, while 4 are projected to decline.

Average annual wages for the middle-ranked occupations in 2007 were much higher ($62,564) than those for all service-providing occupations ($41,610). Wage growth from 2001 to 2007 averaged 3.7 percent per year, faster than the 3.1-percent growth rate for all service-providing occupations. The educational attainment of workers in the middle-ranked occupations also was higher, with 61.7 percent holding a bachelor's or higher degree, compared with 37 percent for all service-providing occupations; only 12.9 percent of workers in the middle group had no more than a high school diploma, as opposed to 32.0 percent of all service-providing workers.

Lowest ranked. The 33 occupations in the least susceptible group accounted for 6.5 million jobs in 2007. (See table 3.) This group consists largely of highly skilled occupations, 30 of which are professional and related occupations or management, business, and financial operations

Table 3.	Employment, projected employment change, educational attainment, and earnings of susceptible occupational categories						
Susceptible occupational categories	Number of occupations	Employment, 2007 (in thousands)	Average annual percent change in employment, projected 2006–16	Percent distribution by educational attainment			Mean annual wages, 2007
				High school	Some college	College	
All service-providing occupations ...	515	117,052	1.1	32.0	31.0	37.0	$41,610
All offshorable occupations	160	30,310	1.2	16.6	29.3	54.0	61,473
Highest ranked occupations	33	9,476	1.1	27.2	42.4	30.4	38,201
Middle-ranked occupations	94	14,306	1.3	12.9	25.4	61.7	62,564
Lowest ranked occupations	33	6,527	1.1	14.0	24.9	61.1	92,868

occupations. Management occupations are heavily represented, accounting for 12 of the 33 in the group. No office and administrative support occupations are included.

Employment of the lowest ranked occupations grew by 1.8 percent per year from 2001 to 2007, faster than the 1.3-percent rate for all service-providing occupations. Employment of the lowest-ranked occupations is projected to grow by 1.1 percent per year from 2006 to 2016, the same rate as that projected for all service-providing occupations. Growth is expected in all but one of these occupations—wholesale and retail buyers, except farm products—which is projected to decline by a negligible amount.

Average annual wages for the least susceptible group in 2007 were $92,868, compared with $41,610 for all service-providing occupations. In addition, the wages for each of the 33 occupations in the least susceptible group were above the average for all service-providing occupations. Wage growth in the group averaged 3.4 percent per year from 2001 to 2007, faster than the 3.1-percent growth rate for all service-providing occupations. Educational attainment of the workers in the least susceptible occupations was high, with 61.1 percent of workers holding a bachelor's or higher degree.

Education groupings.   Another method of analyzing the susceptible occupations is to group them by educational attainment and observe the differences among the groups. During the projections process, analysts assign an education or training category to each occupation.[18] Occupations classified as bachelor's degree or higher were placed into one group, while occupations classified as associate's degree or less were placed into another.[19] Ninety-seven offshorable occupations, accounting for 15.2 million jobs

in 2007, were classified as bachelor's degree or higher, with the remaining 63 offshorable occupations accounting for 15.1 million jobs in 2007. (See table 4.) For comparison purposes, all service-providing occupations also were placed into corresponding education groups.

Over the 2001–07 period, offshorable occupations in the bachelor's-degree-or-higher group grew by 3.0 percent per year, faster than the 2.5-percent growth rate for all bachelor's-degree-or-higher service-providing occupations. (See table 4.) In contrast, offshorable occupations in the associate's-degree-or-less group grew by 0.5 percent per year, slower than the 1.1-percent growth rate for all associate's-degree-or-less service-providing occupations. Offshorable occupations in the bachelor's-degree-or-higher group are projected to grow slightly faster than service-providing occupations in that same group—1.5 percent, compared with 1.4 percent—and offshorable occupations in the associate's-degree-or-less group are projected to grow slightly more slowly than service-providing occupations in that group—0.9 percent, compared with 1.0 percent. Wages in the bachelor's-degree-or-higher offshorable occupations grew by 3.5 percent per year from 2001 to 2007, compared with 3.4 percent for all bachelor's-degree-or-higher service-providing occupations. Wages for the associate's-degree-or-less offshorable occupations grew by 2.9 percent per year over the same period, compared with 2.6 percent for all associate's-degree-or-less service-providing occupations.

THE PHENOMENON OF OFFSHORING, together with its potential effects on the U.S. labor market, has generated much attention. This article does not quantify those effects, but instead attempts to determine the occupations that may be affected by offshoring. The article finds that

Table 4.	Average annual change in employment and wages and projected employment growth, by education group				
Education group	**Number of occupations**	**Employment, 2007 (thousands)**	**Percent change in employment, 2001–07**	**Average annual percent change in wages, 2001–07**	**Average annual percent change in employment, projected 2006–16**
High education, all service-providing occupations...	108	27,337	2.5	3.4	1.4
High education, offshorable occupations.....................	97	15,192	3.0	3.5	1.5
Low education, all service-providing occupations	302	89,715	1.1	2.6	1.0
Low education, offshorable occupations	63	15,118	.5	2.9	.9

NOTE: High education: bachelor's degree or higher; low education: associate's degree or less.

SOURCES: Projected employment change, 2006–16: BLS National Employment Matrix; 2007 employment, and percent change in employment and wages, 2001–07: BLS Occupational Employment Statistics.

160 occupations are susceptible to offshoring and presents considerable data on those occupations. Although the effects of offshoring cannot be measured, it is noteworthy that the offshorable occupations grew slightly faster than all service-providing occupations from 2001 to 2007 and are projected to grow slightly faster than all service-providing occupations from 2006 to 2016. In addition, the offshorable occupations are quite diverse in their job func-

tions, educational attainment, and wages. These findings warrant further research and analysis, but the dearth of additional relevant data, from either the BLS or other sources, makes most conclusions speculative at this point. As a result, the analysis undertaken here attempts only to add to the discourse on offshoring by compiling a list of susceptible occupations, as well as presenting data, both historical and projected, on those occupations. ☐

Notes

[1] In this article, *service-providing occupations* refers to occupations in Standard Occupational Classification (SOC) major groups 11 through 43, 49, and 53. It does not denote the SOC intermediate aggregation service occupations, which cover only major groups 31 through 39. (See table 1.)

[12] *Ibid*., p. 9.

[13] Jensen and Kletzer's analysis covers SOC major groups 11 through 43.

[14] See "Accounting for Offshoring in Occupational Employment Projections," *Occupational Projections and Training Data, 2006–07*, Bulletin 2602 (Bureau of Labor Statistics, February 2006).

[15] Within SOC groups 11 through 43, 49, and 53, all residual occupations were removed before analysis due to the difficulty of accurately defining the job duties of those occupations. In addition, in keeping with the format of the National Employment Matrix—which displays BLS estimates of current and projected employment by detailed industry and detailed occupation—summary occupations were used for postsecondary teachers and for physicians and surgeons. It is unlikely that the various specialties within these occupations differ in the degree to which offshoring affects them.

[16] Figures for 1999 and 2000 are available, but are considered less reliable due to OES methodology. Because data on the survey's full sample of 1.2 million establishments are collected over a period of 3 years—approximately 200,000 establishments every 6 months—the initial 2 years of data do not represent a full sample. The OES survey first adopted the SOC in 1999 and completed its first full sample in 2001.

[17] Full descriptions of all of these data sources are available in *Employment Projections: Occupational Projections and Training Data* (Bureau of Labor Statistics, 2008–09), on the Internet at **www.bls.gov/emp/optd/home.htm**.

[18] Eleven education or training categories are used, ranging from short-term on-the-job training to first professional degree. These categories reflect the most significant source of education or training for each occupation, but certainly not the only source.

[19] In order to prevent the groupings of occupations from being too small, the susceptibility rankings were ignored for this part of the analysis.

APPENDIX: Employment, wages, and education in offshorable occupations

Table A–1.   Data on offshorable occupations: employment and wage variables

SOC code	Occupation title	Susceptibility score	Average annual percent change in employment, 2001–07	Employment, 2007 (thousands)	Average annual percent change in employment, projected 2006–16	Mean annual wages, 2007
	Highest ranked occupations					
15–1021	Computer programmers	16	–3.9	395	–0.4	$72,010

All work, no play for America's workforce

The Big Squeeze: Tough times for the American worker. By Steven Greenhouse, New York, NY, Alfred A. Knopf Publishers, 2008, 303 pp., $25.95/hardback.

"Worked over and overworked" is how Steven Greenhouse, the labor and workplace correspondent for *The New York Times* since 1995, describes the current state of the American workforce. The average American worker is now putting in many more hours annually than his or her European counterpart: 135 additional hours than the typical British worker; 240 hours more than the average French worker; and 370 additional hours (more than 9 weeks) than the typical German worker. These long hours, Greenhouse feels, have led to high levels of stress and fatigue.

In addition to hours worked, Greenhouse reviews historical earnings data and finds that, since 1979, overall real earnings of America's workers have risen just 1 percent after inflation and have actually declined 5 percent for male workers. Median income recently failed to increase for the fifth year in a row after factoring in inflation—a situation which has never occurred before in a time of economic growth. In contrast, from 1979 to 2005 income for Americans in "the top fifth of the food chain" jumped 80 percent and for the top 1 percent it leaped an astronomical 228 percent. Income inequality in the United States, in the author's opinion, has not been this great since the 1920s.

To address their increasingly des-perate situations, Greenhouse notes, millions of American workers have "supersized" their credit cards and/or taken second mortgages on their homes. As a result, many Americans are now spending more than they earn; in 2005, the Nation's personal savings rate dipped below zero for the first time since the Great Depression. As proof of how risky this strategy is, Greenhouse notes that housing fore-closures and personal bankruptcies more than tripled between 1979 and 2004, and the full impact of the sub-prime loan crisis has yet to be felt.

Greenhouse has other concerns for America's workforce as well. The availability of pension plans is declin-ing. Just one-third of laid-off work-ers receive unemployment benefits, down from 50 percent a generation ago. Greenhouse cites a study that found that of 173 nations recently surveyed, the United States was one of only four countries that do not provide paid maternity leave. And, even for those workers fortunate to be covered by health insurance plans, the cost has soared by 83 percent, ac-cording to another source cited by Greenhouse.

What is the origin of the decline in the circumstances of America's workers? Greenhouse focuses on a number of crucial events that he feels tilted the playing field against work-ers: a surge in imports, especially steel and automobiles, which reduced the demand for labor; deregulation poli-cies that hit long-established union-ized companies the hardest; and the firing of 11,500 air traffic controllers in 1981. The Professional Air Traf-fic Controllers union rejected what many felt was a very generous offer that year, including an 11.4-percent 1-year pay increase. Nevertheless, the firing was unprecedented and, Greenhouse believes, set the ground-work for future labor "concessions."

Well-financed corporate raiders also played a negative role, in his opinion, by either taking over strug-gling companies and selling off their assets (and putting their employees out of work) or by walking away with "greenmail." He feels the loss of jobs and job security as a result of corporate downsizing has also hurt the labor movement. Globalization has been tough on America's work-ers as well, especially the outsourcing of America's factories and jobs. Per Greenhouse: "More than any other economic force since the Depres-sion, it is creating havoc for blue col-lar workers and white collar workers alike." Finally, Greenhouse feels that tax cuts since the turn of the 21st century have been unfair and helped widen an already large gap between the working class and the very wealthy.

Greenhouse proposes a wide range of regulatory and policy changes to improve workplaces, working condi-tions, compensation, and retirement, as well as changes to social support programs such as Head Start. From his choice of a title through the top-ics he covers and the changes in eco-nomic and social policies he proposes, Greenhouse's sympathies clearly lie with America's workers and its or-ganized labor movement. For those readers willing to accept his view-points—or at least be challenged by them—I recommend this book.

Bureau of Labor Statistics

Nominations Sought for 2009 Julius Shiskin Award

Nominations are invited for the annual Julius Shiskin Memorial Award for Economic Statistics. The Award is given in recognition of unusually original and important contributions in the development of economic statistics or in the use of statistics in interpreting the economy. Contributions are recognized for statistical research, development of statistical tools, application of information technology techniques, use of economic statistical programs, management of statistical programs, or developing public understanding of measurement issues. The Award was established in 1980 by the Washington Statistical Society (WSS) and is now cosponsored by the WSS, the National Association for Business Economics, and the Business and Economics Statistics Section of the American Statistical Association (ASA). The 2008 award recipients were William R. Bell and Robert M. Groves. Dr. Bell was recognized for his innovative statistical research that led to improved economic statistics through important contributions to the theory and practice of seasonal adjustment, small area estimation, and time series modeling; Dr. Groves was recognized for his innovative statistical research that led to improved economic statistics through important contributions to the theory and practice of survey methods for the conduct of sample surveys of both households and establishments.

Because the program was initiated many years ago, statisticians and economists often ask, "Who was Julius Shiskin?" At the time of his death in 1978, "Julie" was the Commissioner of the Bureau of Labor Statistics (BLS) and earlier served as the Chief Statistician at the Office of Management and Budget (OMB), and the Chief Economic Statistician and Assistant Director of the Census Bureau. Throughout his career, he was known as an innovator. At Census he was instrumental in developing an electronic computer method for seasonal adjustment. In 1961, he published *Signals of Recession and Recovery,* which laid the groundwork for the calculation of monthly economic indicators, and he developed the monthly Census report *Business Conditions Digest* to disseminate them to the public. In 1969, he was appointed Chief Statistician at OMB where he developed the policies and procedures that govern the release of key economic indicators (Statistical Policy Directive Number 3), and originated a *Social Indicators* report. In 1973, he was selected to head BLS where he was instrumental in preserving the integrity and independence of the BLS labor force data and directed the most comprehensive revision in the history of the Consumer Price Index (CPI), which included a new CPI for all urban consumers.

Nominations for the 2009 award are now being accepted. Individuals and groups in the public or private sector from any country can be nominated. The award will be presented with an honorarium of $750 plus additional recognition from the sponsors. A nomination form and a list of all previous recipients are available on the ASA Website at **www.amstat.org/sections/bus_econ/shiskin.html**. For questions or more information, please contact Steven Paben, Julius Shiskin Award Committee Secretary, via e-mail at **paben.steven@bls.gov** or phone at 202–691–6147.

Completed nominations must be *received* by April 1, 2009.

NOTE: Many of the statistics in the following pages were subsequently revised. These pages have not been updated to reflect the revisions.

To obtain BLS data that reflect all revisions, see http://www.bls.gov/data/home.htm

For the latest set of "Current Labor Statistics," see http://www.bls.gov/opub/mlr/curlabst.htm

Current Labor Statistics

Notes on current labor statistics

Notes on Current Labor Statistics

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables 1–14, 17–21, 48, and 52. Seasonally adjusted labor force data in tables 1 and 4–9 and seasonally adjusted establishment survey data shown in tables 1, 12–14, and 17 are revised in the March 2007 *Review*. A brief explanation of the seasonal adjustment methodology appears in "Notes on the data."

Revisions in the productivity data in table 54 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All-Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the "real" earnings shown in table 14—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1982 = 100, the hourly rate expressed in 1982 dollars is $2 ($3/150 x 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1982" dollars.

Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see BLS *Handbook of Methods*, Bulletin 2490. Users also may wish to consult *Major Programs of the Bureau of Labor Statistics*, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau's monthly publication, *Employment and Earnings*. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:

www.bls.gov/cps/

Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:

www.bls.gov/ces/

Additional information on labor force data for areas below the national level are provided in the BLS annual report, *Geographic Profile of Employment and Unemployment*.

For a comprehensive discussion of the Employment Cost Index, see *Employment Cost Indexes and Levels, 1975–95*, BLS Bulletin 2466. The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: *Employee Benefits in Medium and Large Firms; Employee Benefits in Small Private Establishments;* and *Employee Benefits in State and Local Governments*.

More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report* and *Producer Price Indexes*. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the *Monthly Labor Review*. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

www.bls.gov/lpc/

For additional information on international comparisons data, see *International Comparisons of Unemployment,* Bulletin 1979.

Detailed data on the occupational injury and illness series are published in *Occupational Injuries and Illnesses in the United States, by Industry,* a BLS annual bulletin.

Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.
p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data, but also may reflect other adjustments.

Comparative Indicators

(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation

and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

Employment and Unemployment Data

(Tables 1; 4–29)

Household survey data

Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding

4 weeks. Persons who did not look for work because they were on layoff are also counted among the unemployed. **The unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population. Persons **not in the labor force** are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The **civilian noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The **civilian labor force participation** rate is the proportion of the civilian noninstitutional population that is in the labor force. The **employment-population ratio** is employment as a percent of the civilian noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of *Employment and Earnings*. For a discussion of changes introduced in January 2003, see "Revisions to the Current Population Survey Effective in January 2003" in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at **www.bls.gov/cps/rvcps03.pdf**).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See "Revision of Seasonally Adjusted Labor Force Series in 2003," in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at **www.bls.gov/cps/cpsrs.pdf**) for a discussion of the introduction of the use of X-12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the

January–June period. The historical seasonally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July–December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691–6378.

Establishment survey data

Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2002 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goods-producing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private service-providing industries, data are collected for nonsupervisory workers, which include most employees except those in executive,

managerial, and supervisory positions. Those workers mentioned in tables 11–16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private service-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. **Overtime hours** represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The **Diffusion Index** represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

Notes on the data

Establishment survey data are annually adjusted to comprehensive counts of employment (called "benchmarks"). The March 2003 benchmark was introduced in February 2004 with the release of data for January 2004, published in the March 2004 issue of the *Review*. With the release in June 2003, CES completed a conversion from the Standard Industrial Classification (SIC) system to the North American Industry Classification System (NAICS) and completed the transition from its original quota sample design to a probability-based sample design. The industry-coding update included reconstruction of historical estimates in order to preserve

time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the June 2003 issue of *Employment and Earnings* and "Recent changes in the national Current Employment Statistics survey," *Monthly Labor Review*, June 2003, pp. 3–13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of *Employment and Earnings*, and "Recent changes in the State and Metropolitan Area CES survey," *Monthly Labor Review*, June 2003, pp. 14–19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4- versus 5-week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12–17 in the *Review)*. When all returns have been received, the estimates are revised and published as "final" (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Fourth-quarter data are published as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on

establishment survey data, contact the Division of Current Employment Statistics: (202) 691–6555.

Unemployment data by State

Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691–6392 (table 10) or (202) 691–6559 (table 11).

Quarterly Census of Employment and Wages

Description of the series

Employment, wage, and establishment data in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal, agencies subject to the Unemployment Compensation for Federal Employees (UCFE) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Quarterly Census of Employment and Wages (QCEW) data, also referred as ES-202 data, are the most complete enumeration of employment and wage information by industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor

market trends and major industry developments.

Definitions

In general, the Quarterly Census of Employment and Wages monthly employment data represent the number of **covered workers** who worked during, or received pay for, the pay period that included the 12th day of the month. **Covered private industry employment** includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each UI-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (UCFE) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An **establishment** is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different NAICS industries.

Most employers have only one establishment; thus, the establishment is the predominant reporting unit or statistical entity for reporting employment and wages data. Most employers, including State and local governments who operate more than one establishment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly UI report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the UI report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the **installation**: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers. Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into **size** categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level. It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total **wages** paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify that wages be reported for, or based on the period during which services are performed rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as 401(k) plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wage per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual wage is affected by the ratio of full-time to part-time workers as well as the number of individuals in high-paying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of part-time workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

Notes on the data

Beginning with the release of data for 2001, publications presenting data from the Covered Employment and Wages program have switched to the 2002 version of the North

American Industry Classification System (NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Standard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past, the Covered Employment and Wage (CEW) program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England (and New Jersey).

The Office of Management and Budget (OMB) defines metropolitan areas for use in Federal statistical activities and updates these definitions as needed. Data in this table use metropolitan area criteria established by OMB in definitions issued June 30, 1999 (OMB Bulletin No. 99-04). These definitions reflect information obtained from the 1990 Decennial Census and the 1998 U.S. Census Bureau population estimate. A complete list of metropolitan area definitions is available from the National Technical Information Service (NTIS), Document Sales, 5205 Port Royal Road, Springfield, Va. 22161, telephone 1-800-553-6847.

OMB defines metropolitan areas in terms of entire counties, except in the six New England States where they are defined in terms of cities and towns. New England data in this table, however, are based on a county concept defined by OMB as New England County Metropolitan Areas (NECMA) because county-level data are the most detailed available from the Quarterly Census of Employment and Wages. The NECMA is a county-based alternative to the city- and town-based metropolitan areas in New England. The NECMA for a Metropolitan Statistical Area (MSA) include: (1) the county containing the first-named city in that MSA title (this county may include the first-named cities of other MSA, and (2) each additional county having at least half its population in the MSA in which first-named cities are in the county identified in step 1. The NECMA is officially defined areas that are meant to be used by statistical programs that cannot use the regular metropolitan area definitions in New England.

For ADDITIONAL INFORMATION on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691–6567.

Job Openings and Labor Turnover Survey

Description of the series

Data for the **Job Openings and Labor Turnover Survey** (JOLTS) are collected and compiled from a sample of 16,000 business establishments. Each month, data are collected for total employment, job openings, hires, quits, layoffs and discharges, and other separations. The JOLTS program covers all private nonfarm establishments such as factories, offices, and stores, as well as Federal, State, and local government entities in the 50 States and the District of Columbia. The JOLTS sample design is a random sample drawn from a universe of more than eight million establishments compiled as part of the operations of the Quarterly Census of Employment and Wages, or QCEW, program. This program includes all employers subject to State unemployment insurance (UI) laws and Federal agencies subject to Unemployment Compensation for Federal Employees (UCFE).

The sampling frame is stratified by ownership, region, industry sector, and size class. Large firms fall into the sample with virtual certainty. JOLTS total employment estimates are controlled to the employment estimates of the Current Employment Statistics (CES) survey. A ratio of CES to JOLTS employment is used to adjust the levels for all other JOLTS data elements. Rates then are computed from the adjusted levels.

The monthly JOLTS data series begin with December 2000. Not seasonally adjusted data on job openings, hires, total separations, quits, layoffs and discharges, and other separations levels and rates are available for the total nonfarm sector, 16 private industry divisions and 2 government divisions based on the North American Industry Classification System (NAICS), and four geographic regions. Seasonally adjusted data on job openings, hires, total separations, and quits levels and rates are available for the total nonfarm sector, selected industry sectors, and four geographic regions.

Definitions

Establishments submit **job openings** information for the last business day of the reference month. A job opening requires that (1) a specific position exists and there is work available for that position; and (2) work could start within 30 days regardless of whether a suitable candidate is found; and (3) the employer is actively recruiting from outside the establishment to fill the position. Included are full-time, part-time, permanent, short-term, and seasonal openings. Active recruiting means that the establishment is taking steps to fill a position by advertising in newspapers or on the Internet, posting help-wanted signs, accepting applications, or using other similar methods.

Jobs to be filled only by internal transfers, promotions, demotions, or recall from layoffs are excluded. Also excluded are jobs with start dates more than 30 days in the future, jobs for which employees have been hired but have not yet reported for work, and jobs to be filled by employees of temporary help agencies, employee leasing companies, outside contractors, or consultants. The job openings rate is computed by dividing the number of job openings by the sum of employment and job openings, and multiplying that quotient by 100.

Hires are the total number of additions to the payroll occurring at any time during the reference month, including both new and rehired employees and full-time and part-time, permanent, short-term and seasonal employees, employees recalled to the location after a layoff lasting more than 7 days, on-call or intermittent employees who returned to work after having been formally separated, and transfers from other locations. The hires count does not include transfers or promotions within the reporting site, employees returning from strike, employees of temporary help agencies or employee leasing companies, outside contractors, or consultants. The hires rate is computed by dividing the number of hires by employment, and multiplying that quotient by 100.

Separations are the total number of terminations of employment occurring at any time during the reference month, and are reported by type of separation—quits, layoffs and discharges, and other separations. Quits are voluntary separations by employees (except for retirements, which are reported as other separations). Layoffs and discharges are involuntary separations initiated by the employer and include layoffs with no intent to rehire, formal layoffs lasting or expected to last more than 7 days, discharges resulting from mergers, downsizing, or closings, firings or other discharges for cause, terminations of permanent or short-term employees, and terminations of seasonal employees. Other separations include retirements, transfers to other locations, deaths, and separations due to disability. Separations do not include transfers within the same location or employees on strike.

The separations rate is computed by dividing the number of separations by employment, and multiplying that quotient by 100. The quits, layoffs and discharges, and other separations rates are computed similarly, dividing the number by employment and multiplying by 100.

Notes on the data

The JOLTS data series on job openings, hires, and separations are relatively new. The full sample is divided into panels, with one panel enrolled each month. A full complement of panels for the original data series based on the 1987 Standard Industrial Classification (SIC) system was not completely enrolled in the survey until January 2002. The supple-mental panels of establishments needed to create NAICS estimates were not completely enrolled until May 2003. The data collected up until

those points are from less than a full sample. Therefore, estimates from earlier months should be used with caution, as fewer sampled units were reporting data at that time.

In March 2002, BLS procedures for collecting hires and separations data were revised to address possible underreporting. As a result, JOLTS hires and separations estimates for months prior to March 2002 may not be comparable with estimates for March 2002 and later.

The Federal Government reorganization that involved transferring approximately 180,000 employees to the new Department of Homeland Security is not reflected in the JOLTS hires and separations estimates for the Federal Government. The Office of Personnel Management's record shows these transfers were completed in March 2003. The inclusion of transfers in the JOLTS definitions of hires and separations is intended to cover ongoing movements of workers between establishments. The Department of Homeland Security reorganization was a massive one-time event, and the inclusion of these intergovernmental transfers would distort the Federal Government time series.

Data users should note that seasonal adjustment of the JOLTS series is conducted with fewer data observations than is customary. The historical data, therefore, may be subject to larger than normal revisions. Because the seasonal patterns in economic data series typically emerge over time, the standard use of moving averages as seasonal filters to capture these effects requires longer series than are currently available. As a result, the stable seasonal filter option is used in the seasonal adjustment of the JOLTS data. When calculating seasonal factors, this filter takes an average for each calendar month after detrending the series. The stable seasonal filter assumes that the seasonal factors are fixed; a necessary assumption until sufficient data are available. When the stable seasonal filter is no longer needed, other program features also may be introduced, such as outlier adjustment and extended diagnostic testing. Additionally, it is expected that more series, such as layoffs and discharges and additional industries, may be seasonally adjusted when more data are available.

JOLTS hires and separations estimates cannot be used to exactly explain net changes in payroll employment. Some reasons why it is problematic to compare changes in payroll employment with JOLTS hires and separations, especially on a monthly basis, are: (1) the reference period for payroll employment is the pay period including the 12th of the month, while the reference period for hires and separations is the calendar month; and

(2) payroll employment can vary from month to month simply because part-time and on-call workers may not always work during the pay period that includes the 12th of the month. Additionally, research has found that some reporters systematically underreport separations relative to hires due to a number of factors, including the nature of their payroll systems and practices. The shortfall appears to be about 2 percent or less over a 12-month period.

FOR ADDITIONAL INFORMATION on the Job Openings and Labor Turnover Survey, contact the Division of Administrative Statistics and Labor Turnover at (202) 961–5870.

Compensation and Wage Data

(Tables 1–3; 30–37)

The National Compensation Survey (NCS) produces a variety of compensation data. These include: The Employment Cost Index (ECI) and NCS benefit measures of the incidence and provisions of selected employee benefit plans. Selected samples of these measures appear in the following tables. NCS also compiles data on occupational wages and the Employer Costs for Employee Compensation (ECEC).

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It is a Laspeyres Index that uses fixed employment weights to measure change in labor costs free from the influence of employment shifts among occupations and industries.

The ECI provides data for the civilian economy, which includes the total private nonfarm economy excluding private households, and the public sector excluding the Federal government. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Sample establishments are classified by industry categories based on the 2002 North American Classification System (NAICS). Within a sample establishment, specific job categories are selected and classified into about 800 occupations according to the 2000 Standard Occupational Classification (SOC) System. Individual occupations are com-

bined to represent one of ten intermediate aggregations, such as professional and related occupations, or one of five higher level aggregations, such as management, professional, and related occupations.

Fixed employment weights are used each quarter to calculate the most aggregate series—civilian, private, and State and local government. These fixed weights are also used to derive all of the industry and occupational series indexes. Beginning with the March 2006 estimates, 2002 fixed employment weights from the Bureau's Occupational Employment Statistics survey were introduced. From March 1995 to December 2005, 1990 employment counts were used. These fixed weights ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the series based on bargaining status, census region and division, and metropolitan area status, fixed employment data are not available. The employment weights are reallocated within these series each quarter based on the current ECI sample. The indexes for these series, consequently, are not strictly comparable with those for aggregate, occupational, and industry series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The ECI data in these tables reflect the con-version to the 2002 North American Industry Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. ECI series based on NAICS and SOC became the official BLS estimates starting in March 2006.

The ECI for changes in wages and salaries

in the private nonfarm economy was published beginning in 1975. Changes in total compensation cost—wages and salaries and benefits combined—were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (December 2005=100) are available on the Internet: **www.bls.gov/ect/**

ADDITIONAL INFORMATION on the Employment Cost Index is available at **www.bls.gov/ncs/ect/home.htm** or by telephone at (202) 691–6199.

National Compensation Survey Benefit Measures

Description of the series

NCS benefit measures of employee benefits are published in two separate reports. The annual summary provides data on the incidence of (access to and participation in) selected benefits and provisions of paid holidays and vacations, life insurance plans, and other selected benefit programs. Data on percentages of establishments offering major employee benefits, and on the employer and employee shares of contributions to medical care premiums also are presented. Selected benefit data appear in the following tables. A second publication, published later, contains more detailed information about health and retirement plans.

Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Employees are considered as having **access** to a benefit plan if it is available for their use. For example, if an employee is permitted to participate in a medical care plan offered by the employer, but the employee declines to do so, he or she is placed in the category with those having access to medical care.

Employees in contributory plans are considered as **participating** in an insurance or retirement plan if they have paid required

contributions and fulfilled any applicable service requirement. Employees in noncontributory plans are counted as participating regardless of whether they have fulfilled the service requirements.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

Notes on the data

ADDITIONAL INFORMATION ON THE NCS benefit measures is available at **www.bls.gov/ncs/ebs/home.htm** or by telephone at (202) 691–6199.

Work stoppages

Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 37.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate

number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

ADDITIONAL INFORMATION on work stop-pages data is available at **www. bls. gov/cba/home.htm** or by telephone at (202) 691–6199.

Price Data

(Tables 2; 38–46)

Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period—December 2003 = 100 for many Producer Price Indexes (unless otherwise noted), 1982–84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 = 100 for International Price Indexes.

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993–95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 14 major urban centers are presented in table 39. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are meaured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691–7000.

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in

accordance with the 2002 North American Industry Classification System and product codes developed by the U.S. Census Bureau.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691–7705.

International Price Indexes

Description of the series

The **International Price Program** produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S.

border for imports. For nearly all products, the prices refer to transactions completed during the first week of the month. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard International Trade Classification (SITC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691–7155.

Productivity Data

(Tables 2; 47–50)

Business and major sectors

Description of the series

The productivity measures relate real output to real input. As such, they encompass a fam-ily of measures which include single-factor input measures, such as output per hour, output per unit of labor input, or output per unit of capital input, as well as measures of multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the quantity of goods and services produced per unit of capital services input. **Multifactor productivity** is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 47–50 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity, energy, material, and research and development; the organi-

zation of production; managerial skill; and characteristics and efforts of the work force.

Industry productivity measures

Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, **output** indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The **labor input** series is based on the hours of all workers or, in the case of some transportation industries, on the number of employees. For most industries, the series consists of the hours of all employees. For some trade and services industries, the series also includes the hours of partners, proprietors, and unpaid family workers.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. **Labor compensation** includes payroll as well as supplemental payments, including both legally required expenditures and payments for voluntary programs.

Multifactor productivity is derived by dividing an index of industry output by an index of combined inputs consumed in producing that output. **Combined inputs** include capital, labor, and intermediate purchases. The measure of **capital input** represents the flow of services from the capital stock used in production. It is developed from measures

of the net stock of physical assets—equipment, structures, land, and inventories. The measure of **intermediate purchases** is a combination of purchased materials, services, fuels, and electricity.

Notes on the data

The industry measures are compiled from data produced by the Bureau of Labor Statistics and the Census Bureau, with additional data supplied by other government agencies, trade associations, and other sources.

International Comparisons

(Tables 51–53)

Labor force and unemployment

Description of the series

Tables 51 and 52 present comparative measures of the labor force, employment, and unemployment approximating U.S. concepts for the United States, Canada, Australia, Japan, and six European countries. The Bureau adjusts the figures for these selected countries, for all known major definitional differences, to the extent that data to prepare adjustments are available. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For further information on adjustments and comparability issues, see Constance Sorrentino, "International unemployment rates: how comparable are they?" *Monthly Labor Review,* June 2000, pp. 3–20, available on the Internet at **www.bls.gov/opub/mlr/2000/06/art1full.pdf**.

Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

Notes on the data

Foreign country data are adjusted as closely as possible to the U.S. definitions. Primary areas of adjustment address conceptual differences in upper age limits and defini-

tions of employment and unemployment, provided that reliable data are available to make these adjustments. Adjustments are made where applicable to include employed and unemployed persons above upper age limits; some European countries do not include persons older than age 64 in their labor force measures, because a large portion of this population has retired. Adjustments are made to exclude active duty military from employment figures, although a small number of career military may be included in some European countries. Adjustments are made to exclude unpaid family workers who worked fewer than 15 hours per week from employment figures; U.S. concepts do not include them in employment, whereas most foreign countries include all unpaid family workers regardless of the number of hours worked. Adjustments are made to include full-time students seeking work and available for work as unemployed when they are classified as not in the labor force.

Where possible, lower age limits are based on the age at which compulsory schooling ends in each country, rather than based on the U.S. standard of 16. Lower age limits have ranged between 13 and 16 over the years covered; currently, the lower age limits are either 15 or 16 in all 10 countries.

Some adjustments for comparability are not made because data are unavailable for adjustment purposes. For example, no adjustments to unemployment are usually made for deviations from U.S. concepts in the treatment of persons waiting to start a new job or passive jobseekers. These conceptual differences have little impact on the measures. Furthermore, BLS studies have concluded that no adjustments should be made for persons on layoff who are counted as employed in some countries because of their strong job attachment as evidenced by, for example, payment of salary or the existence of a recall date. In the United States, persons on layoff have weaker job attachment and are classified as unemployed.

The annual labor force measures are obtained from monthly, quarterly, or continuous household surveys and may be calculated as averages of monthly or quarterly data. Quarterly and monthly unemployment rates are based on household surveys. For some countries, they are calculated by applying annual adjustment factors to current published data and, therefore, are less precise indicators of unemployment under U.S. concepts than the annual figures. The labor force measures may have breaks in series over time due to changes in surveys, sources, or estimation methods. Breaks are noted in data tables.

For up-to-date information on adjustments and breaks in series, see the Technical

Notes of *Comparative Civilian Labor Force Statistics, 10 Countries*, on the Internet at **www.bls.gov/fls/flscomparelf.htm**, and the Notes of *Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted*, on the Internet at **www.bls.gov/fls/flsjec.pdf**.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Foreign Labor Statistics: (202) 691-5654 or **flshelp@ bls.gov.**

Manufacturing productivity and labor costs

Description of the series

Table 53 presents comparative indexes of manufacturing output per hour (labor productivity), output, total hours, compensation per hour, and unit labor costs for the United States, Australia, Canada, Japan, the Republic of Korea, Taiwan, and 10 European countries. These measures are trend comparisons—that is, series that measure changes over time— rather than level comparisons. BLS does *not* recommend using these series for level comparisons because of technical problems.

BLS constructs the comparative indexes from three basic aggregate measures—output, total labor hours, and total compensation. The hours and compensation measures refer to employees (wage and salary earners) in Belgium and Taiwan. For all other economies, the measures refer to all employed persons, including employees, self-employed persons, and unpaid family workers.

The data for recent years are based on the United Nations System of National Accounts 1993 (SNA 93). Manufacturing is generally defined according to the International Standard Industrial Classification (ISIC). However, the measures for France include parts of mining as well. For the United States and Canada, it is defined according to the North American Industry Classification System (NAICS 97).

Definitions

Output. For most economies, the output measures are real value added in manufacturing from national accounts. However, output for Japan prior to 1970 and for the Netherlands prior to 1960 are indexes of industrial production. The manufacturing value added measures for the United Kingdom are essentially identical to their indexes of industrial production.

For United States, the output measure for the manufacturing sector is a chain-weighted index of real gross product originating (deflated value added) produced by the Bureau of Economic Analysis of the U.S. Department of Commerce. Most of the other economies now also use chain-weighted as opposed to a fixed-year weights that are periodically updated.

To preserve the comparability of the U.S. measures with those of other economies, BLS uses gross product originating in manufacturing for the United States. The gross product originating series differs from the manufacturing output series that BLS publishes in its quarterly news releases on U.S. productivity and costs (and that underlies the measures that appear in tables 48 and 50 in this section). The quarterly measures are on a "sectoral output" basis, rather than a value-added basis. Sectoral output is gross output less intrasector transactions.

Total hours refer to hours worked in all economies. The measures are developed from statistics of manufacturing employment and average hours. For most other economies, recent years' aggregate hours series are obtained from national statistical offices, usually from national accounts. However, for some economies and for earlier years, BLS calculates the aggregate hours series using employment figures published with the national accounts, or other comprehensive employment series, and data on average hours worked.

Hourly compensation is total compensation divided by total hours. Total compensation includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. For Australia, Canada, France, and Sweden, compensation is increased to account for important taxes on payroll or employment. For the United Kingdom, compensation is reduced between 1967 and 1991 to account for subsidies.

Labor productivity is defined as real output per hour worked. Although the labor productivity measure presented in this release relates output to the hours worked of persons employed in manufacturing, it does not measure the specific contributions of labor as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology, capital investment, capacity utilization, energy use, and managerial skills, as well as the skills and efforts of the workforce.

Unit labor costs are defined as the cost of labor input required to produce one unit of output. They are computed as compensation in nominal terms divided by real output. Unit labor costs can also be computed by dividing hourly compensation by output per hour, that is, by labor productivity.

Notes on the data

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

Occupational Injury and Illness Data

(Tables 54–55)

Survey of Occupational Injuries and Illnesses

Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers' job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal

condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both, because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

Notes on the data

The definitions of occupational injuries and illnesses are from *Recordkeeping Guidelines for Occupational Injuries and Illnesses* (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In

contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, *Occupational Injuries and Illnesses: Counts, Rates, and Characteristics.*

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691–6180, or access the Internet at: **www.bls. gov/iif/**

Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including

death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety and Health Administration records, medical examiner and autopsy reports, media accounts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses, which can be difficult to identify due to long latency periods.

Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 691–6175, or the Internet at: **www.bls.gov/iif/**

[1] Quarterly data seasonally adjusted.

[2] Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter.

[3] The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

[4] Excludes Federal and private household workers.

[5] Goods-producing industries include mining, construction, and manufacturing. Service-providing industries include all other private sector industries.

NOTE: Beginning in January 2003, household survey data reflect revised population controls. Nonfarm data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with SIC based data.

[1] Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter. Compensation and price data are not seasonally adjusted, and the price data are not compounded.

[2] Excludes Federal and private household workers.

[3] The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes

only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

[4] Annual rates of change are computed by comparing annual averages. Quarterly percent changes reflect annual rates of change in quarterly indexes. The data are seasonally adjusted.

[5] Output per hour of all employees.

3. Alternative measures of wage and compensation changes

[1] The population figures are not seasonally adjusted.

[2] Civilian employment as a percent of the civilian noninstitutional population.

[3] Beginning in 2003, persons who selected this race group only; persons who selected more than one race group are not included. Prior to 2003, persons who reported more than one race were included in the group they identified as the main race.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in January 2003, data reflect revised population controls used in the household survey.

[1] Average weekly wages were calculated using unrounded data.

[2] Percent changes were computed from quarterly employment and pay data adjusted for noneconomic county reclassifications. See Notes on Current Labor Statistics.

[3] Totals for the United States do not include data for Puerto Rico or the Virgin Islands.

[4] Data do not meet BLS or State agency disclosure standards.

NOTE: Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs. Data are preliminary.

23. Quarterly Census of Employment and Wages: by State, first quarter 2008.

[1] Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs.

[2] Includes data for Metropolitan Statistical Areas (MSA) as defined by OMB Bulletin No. 04-03 as of February 18, 2004.

[3] Each year's total is based on the MSA definition for the specific year. Annual changes include differences resulting from changes in MSA definitions.

[4] Totals do not include the six MSAs within Puerto Rico.

27. Annual data: Employment status of the population

[Numbers in thousands]

Employment status	1997	1998[1]	1999[1]	2000[1]	2001[1]	2002	2003	2004	2005	2006	2007

[1] Cost (cents per hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

[2] Consists of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

NOTE: The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

[1] The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC) System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.

[2] The white-collar and blue-collar occupation series were discontinued effective 2007.

[3] The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.

Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

Percent of estalishments offering healthcare benefits …………………..........	58	61	63	62	60
Percentage of medical premium paid by					
Employer and Employee					
Single coverage					
Employer share………………………………………	82	82	82	82	81
Employee share………………………………………	18	18	18	18	19
Family coverage					
Employer share………………………………………	70	69	71	70	71
Employee share………………………………………	30	31	29	30	29

[1] The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC) System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.

[2] The white-collar and blue-collar occupation series were discontinued effective 2007.

[3] The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.

Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

**36. National Compensation Survey: Percent of workers in private industry
with access to selected benefits, 2003-2007**

Benefit	Year				
	2003	2004	2005	2006	2007
Life insurance……………………………………………	50	51	52	52	58
Short-term disabilty insurance…………………………	39	39	40	39	39

[1] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

M—Every month.

1—January, March, May, July, September, and November.

2—February, April, June, August, October, and December.

[2] Regions defined as the four Census regions.

[3] Indexes on a December 1996 = 100 base.

[4] The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.

[5] Indexes on a December 1986 = 100 base.

[6] In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the *CPI Detailed*

Report: Anchorage, AK; Cincinnatti, OH–KY–IN; Kansas City, MO–KS; Milwaukee–Racine, WI; Minneapolis–St. Paul, MN–WI; Pittsburgh, PA; Port-land–Salem, OR–WA; St Louis, MO–IL; San Diego, CA; Tampa–St. Petersburg–Clearwater, FL.

[7] Indexes on a November 1996 = 100 base.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date. Dash indicates data not available.

NOTE: Dash indicates data not available.

Quarterly figures for France, Germany, Italy, and the Netherlands are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures. Quarterly figures for Sweden are BLS seasonally adjusted estimates derived from Swedish not seasonally adjusted data.

For further qualifications and historical annual data, see the BLS report *Comparative Civilian Labor Force Statistics, 10 Countries* (on the Internet at **http://www.bls.gov/fls/flscomparelf.htm**). For monthly unemployment rates, as well as the quarterly and annual rates published in this table, see the BLS report *Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted* (on the Internet at **http://www.bls.gov/fls/flsjec.pdf**). Unemployment rates may differ between the two reports mentioned, because the former is updated semi-annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.

52. Annual data: employment status of the working-age population, approximating U.S. concepts, 10 countries

[1] Labor force as a percent of the working-age population.

[2] Employment as a percent of the working-age population.

NOTE: Dash indicates data not available.
There are breaks in series for the United States (1998, 1999, 2000, 2003, 2004), Australia (2001), Germany (1999, 2005), the Netherlands (2000), and Sweden (2005). For further qualifications and historical annual data, see the BLS report *Comparative*

Civilian Labor Force Statistics, 10 Countries (on the Internet at **http://www.bls.gov/fls/flscomparelf.htm**). Unemployment rates may differ from those in the BLS report *Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted* (on the Internet at **http://www.bls.gov/fls/flsjec.pdf**), because the former is updated semi-annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.

53. Annual indexes of manufacturing productivity and related measures, 16 economies

[1] Data for 1989 and subsequent years are based on the *Standard Industrial Classification Manual*, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985–88, which were based on the *Standard Industrial Classification Manual*, 1972 Edition, 1977 Supplement.

[2] Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.

[3] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays;

EH = total hours worked by all employees during the calendar year; and

200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year).

[4] Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.

[5] Excludes farms with fewer than 11 employees since 1976.

NOTE: Dash indicates data not available.

55. Fatal occupational injuries by event or exposure, 1996-2005

Event or exposure[1]	1996-2000 (average)	2001-2005 (average)[2]	2005[3] Number	2005[3] Percent
All events	6,094	5,704	5,734	100
Transportation incidents	2,608	2,451	2,493	43
Highway	1,408	1,394	1,437	25

Fires and explosions	196	174	159	3
Fires--unintended or uncontrolled	103	95	93	2
Explosion	92	78	65	1

[1] Based on the 1992 BLS Occupational Injury and Illness Classification Manual.

[2] Excludes fatalities from the Sept. 11, 2001, terrorist attacks.

[3] The BLS news release of August 10, 2006, reported a total of 5,702 fatal work injuries for calendar year 2005. Since then, an additional 32 job-related fatalities were identified, bringing the total job-related fatality count for 2005 to 5,734.

NOTE: Totals for all years are revised and final. Totals for major categories may include subcategories not shown separately. Dashes indicate no data reported or data that do not meet publication criteria. N.e.c. means "not elsewhere classified."

Monthly Labor Review
Index to Volume 131
JANUARY–DECEMBER 2008
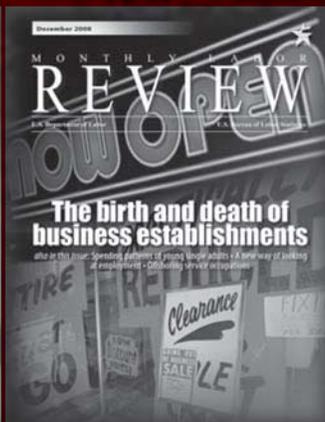

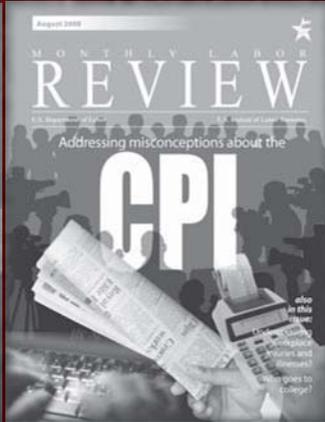

Index to Volume 131
January 2008 to December 2008

Youth enrollment and employment during the school year. 2008 Feb. 51–63.

Elderly

Experimental consumer price index for elderly Americans (CPI-E): 1982–2007, The. 2008 Apr. 19–24.

Older workers: increasing their labor force participation and hours of work. 2008 Jan. 41–54.

Employment (See also Labor force, Labor market, and Unemployment.)

Business Processes and Business Functions: a new way of looking at employment. 2008 Dec. 51–70.

Effect of business ownership change on occupational employment and wages, The. 2008 Sept. 3–23.

Employment characteristics of Gulf War-era II veterans in 2006: a visual essay. 2008 May 3–13.

Employment programs for recipients of unemployment insurance. 2008 Oct. 17–27.

Employment rate of people with disabilities, The. 2008 Nov. 44–50.

Household survey indicators weaken in 2007. 2008 Mar. 3–18.

Multiple jobholding in States in 2007. 2008 Sept. 52–53.

Occupational employment in the not-for-profit sector. 2008 Nov. 11–43.

Payroll employment in 2007: job growth slows. 2008 Mar. 19–31.

Takeoff and descent of airline employment. 2008 Oct. 3–16.

Youth enrollment and employment during the school year. 2008 Feb. 51–61.

Employment Cost Index

Employers' health insurance cost burden, 1996–2005. 2008 June 28–44.

Transitional Employment Cost Indexes for seasonal adjustment. 2008 Apr. 25–39.

Energy

An analysis of Southern energy expenditures and prices, 1984–2006. 2008 Apr. 3–18.

Producer inflation accelerates in 2007 due to rising prices for energy and foods. 2008 July 3–18.

Entrepreneurship

Births and deaths of business establishments in the United States, The, 2008 Dec. 3–18.

Europe

Gender and nonstandard work hours in 12 European countries. 2008 Feb. 83–103.

Expenditures

An analysis of Southern energy expenditures and prices, 1984–2006. 2008 Apr. 3–18.

Expenditure patterns of young single adults: two recent generations compared. 2008 Dec. 19–50.

Finland

Gender and nonstandard work hours in 12 European countries. 2008 Feb. 83–103.

France

Gender and nonstandard work hours in 12 European countries. 2008 Feb. 83–103.

Health and insurance plans

Employers' health insurance cost burden, 1996–2005. 2008 June 28–44.

Hours of work

Gender and nonstandard work hours in 12 European countries. 2008 Feb. 83–103.

Teachers' work patterns: when, where, and how much do U.S. teachers work? 2008 Mar. 52–59.

Hurricane Katrina

Hurricane Katrina evacuees: who they are, where they are, and how they are faring. 2008 Mar. 32–51.

Industry (General)

Labor productivity trends since 2000, by sector and industry. 2008 Feb. 64–82.

Takeoff and descent of airline employment. 2008 Oct. 3–16.

Inflation

Producer inflation accelerates in 2007 due to rising prices for energy and foods. 2008 July 3–18.

Injuries (See Work injuries and illnesses.)

Insurance (See Health and insurance plans.)

International Price Program (IPP)

Price measures of new vehicles: a comparison. 2008 July 19–32.

Internet

A hedonic model for Internet access service in the Consumer Price Index. 2008 July 33–48.

Ireland

Gender and nonstandard work hours in 12 European countries. 2008 Feb. 83–103.

Italy

Gender and nonstandard work hours in 12 European countries. 2008 Feb. 83–103.

Job creation

The births and deaths of business establishments in the United States. 2008 Dec. 3–18.

Job Openings and Labor Turnover Survey (JOLTS)

Job openings, hires, and turnover decrease in 2007. 2008 May 14–23.

Studying the labor market using BLS labor dynamics data. 2008 Feb. 3–16.

Labor force (See also Employment and Unemployment.)

Household survey indicators weaken in 2007. 2008 Mar. 3–18.

Knowing younger workers better: information from the NLSY97. 2008 Sept. 42–51.
