U.S. Bureau of Labor Statistics
Keith Hall, Commissioner

The *Monthly Labor Review* is published monthly by the Bureau of Labor Statistics of the U.S. Department of Labor. The *Review* welcomes articles on employment and unemployment, compensation and working conditions, the labor force, labor-management relations, productivity and technology, occupational safety and health, demographic trends, and other economic developments.

The *Review's* audience includes economists, statisticians, labor relations practitioners (lawyers, arbitrators, etc.), sociologists, and other professionals concerned with labor related issues. Because the *Review* presents topics in labor economics in less forbidding formats than some social science journals, its audience also includes laypersons who are interested in the topics, but are not professionally trained economists, statisticians, and so forth.

In writing articles for the *Review*, authors should aim at the generalists in the audience on the assumption that the specialist will understand. Authors should use the simplest exposition of the subject consonant with accuracy and adherence to scientific methods of data collection, analysis, and drawings of conclusions. Papers should be factual and analytical, not polemical in tone. Potential articles, as well as communications on editorial matters, should be submitted to:

The November Review

You know that times are tough when an economic downturn gets its own nickname. The so-called Great Recession, which the business-cycle arbiters have determined began in December 2007 and ended in June 2009, is the subject of our first article this month. Andrew Sum and Ishwar Khatiwada, affiliated with the Center for Labor Market Studies at Northeastern University, focus on the trend in underemployment associated with the business-cycle contraction. Data are collected in the Current Population Survey (CPS) on employed people who work full time (35 or more hours per week), part time voluntarily, and part time for economic reasons. Among the last-named group, the authors deem those who want full-time jobs and are available for full-time work to be “underemployed.” Such workers are the primary subject of their analysis of CPS data.

Just before the onset of the recession, there were an estimated 4.2 million underemployed workers nationally. From that time to about a year later, the fourth quarter of 2008, the number rose sharply, to 7.2 million. And it continued to rise even further, reaching 8.9 million a year after that. As the authors point out, the increases in the number and percent of these workers were the highest in any 2-year period since the end of World War II.

Additional CPS data were analyzed by the authors to deepen our understanding of who these underemployed workers were. Workers in nearly every major age group and racial or ethnic group saw their underemployment rates more than double over the years examined. All the major educational attainment groups also saw

their underemployment rates more than double, although the percentage changes varied widely. As is so often the case with educational attainment differentials, people without a high school diploma or GED diploma suffered the most adverse effects: they were much more likely to be underemployed than their peers with high school or GED diplomas or college degrees. There were also notable differentials by industry, occupation, and household income.

Sum and Khatiwada conclude by examining the costs of underemployment, in terms of national aggregates of earnings and taxes, and examining the considerable likelihood of the underemployed receiving lower levels of employee benefits from their employers, such as health insurance and pensions. As contemporary analysts and economic historians assess the full impact of this recession, this article could be useful in illuminating the changes affecting one portion of the labor market.

Another article this month, by Diane J. Macunovich, a professor at the University of Redlands, steps away from the current-period focus of our first article and takes a look at trends in women’s labor supply in the United States over the last three decades. As has frequently been noted, the labor force participation of women grew strongly as in the 1980s and somewhat less so in the 1990s. The first decade of the 21st century has seen a reversal in that trend of growth. The author presents an array of labor force participation data for women, including data by age, educational attainment, marital status, and the presence of children, in order to shed light on a phenomenon that reflects changing demographics, economics, and workplace attitudes and perceptions.

Our November issue wraps up with a report from BLS economist Stephen Pegula on fatal occupational injuries at road construction sites over the 2003–07 period.

Focus on Prices and Spending

The Bureau has recently released the latest editions in its quarterly series Focus on Prices and Spending. One issue compares household energy spending as measured by BLS’ Consumer Expenditure Survey with that measured by the Residential Energy Consumption Survey sponsored by the Energy Information Administration. (This report is available at http://www.bls.gov/opub/focus/volume1_number12/cex_1_12.pdf.) Another issue asks, “What does the Producer Price Index measure?” (http://www.bls.gov/opub/focus/volume1_number9/ppi_1_9.pdf). The remaining two issues describe the use of the Consumer Price Index in calculating Social Security cost-of-living adjustments (http://www.bls.gov/opub/focus/volume1_number10/cpi_1_10.pdf) and the impact of the European debt crisis on U.S. import prices (http://www.bls.gov/opub/focus/volume1_number11/ipp_1_11.pdf). Taken together, these reports provide an interesting and somewhat eclectic look at the far-reaching effects of the behavior of prices and price measures.

The Nation’s underemployed in the “Great Recession” of 2007–09

Data from the Current Population Survey show that the less educated, those in low-skilled occupations, and those in low-paying occupations had a higher incidence of underemployment during the 2007–09 recession; an examination of the U.S. income distribution reveals that underemployment is more concentrated among workers from lower income households

Andrew Sum
and
Ishwar Khatiwada

The Nation’s labor markets were deeply affected by the deteriorating economic conditions that began in December 2007 and continued for the next 2 years. Some analysts have referred to this period as the “Great Recession” of 2007–09. Despite what appears to have been a technical end to the recession in the summer of 2009,¹ in the second half of that year labor market problems of workers continued to worsen. Both formal payroll and civilian employment levels continued to fall through the end of 2009, and the unemployment rate remained at or slightly above 10 percent in the last 3 months of the year.² Besides the high unemployment rate, underemployment has increased markedly over the past 2 years, driving up the Nation’s overall labor underutilization rate, especially among teens and young adults, the less educated, Black and Hispanic men, and blue-collar workers.³

This article identifies and assesses changes in the size and demographic and socioeconomic composition of the Nation’s underemployed workers during the course of the recession of 2007–09. Comparing recent trends in the numbers of underemployed workers with those in the previous three recessions (2001, 1990–91, and 1981–

82) and over the entire 1994–2009 period, the article goes on to identify the magnitude of the losses in hours worked, weekly earnings, and aggregate annual earnings due to the rise in underemployment during the recession (through the fourth quarter of 2009). Although the growth in the national pool of underemployed workers has received some attention from labor market analysts and from the national and local media, little attention has been paid to who these underemployed workers are, what types of jobs they hold, and the size of their weekly hours and earnings losses. The analysis that follows seeks to overcome this absence of detailed information, because at no time over the past 30 years has underemployment been so big a problem. It begins with a review of the existing monthly measures of underemployment in the United States from the Current Population Survey (CPS), a national household survey conducted by the U.S. Bureau of the Census for the U.S. Bureau of Labor Statistics (BLS).

Underemployment

The CPS, a national survey of some 60,000 households, is used to estimate the size of the U.S. civilian labor force and its employed and unemployed populations. Labor force data are collected from all household members of

Andrew Sum is the director of, and Ishwar Khatiwada is a senior research associate at, the Center for Labor Market Studies, Northeastern University, Boston, MA. Email: a.sum@neu.edu or i.khatiwada@neu.edu

working age (16 years and older) in the civilian non-institutional population.⁴ On the basis of their answers to the labor force activity questions, respondents are assigned to one of the following three mutually exclusive categories: employed, unemployed, and not in the labor force. In November 2009, of the 236.7 million persons in the civilian noninstitutional population, approximately 153.5 million, or just under 65 percent, were active members of the civilian labor force (the employed and the unemployed). Of these labor force participants, 14.4 million, or 9.4 percent, were unemployed in November.⁵

The CPS labor force questionnaire also is used to collect detailed information on the characteristics of the jobs held by the employed, including their weekly hours of work, their hourly and weekly earnings, the occupations and industries in which they are employed, and the reasons they are working part time (less than 35 hours per week). The employed are classified into three groups on the basis of their hours of work and their reasons for working part time: the full-time employed (those working 35 or more hours per week), those working part time voluntarily, and, of prime focus in this article, *those working part time for economic reasons*, such as slack demand for work at their firm, poor business conditions, or an inability to find a full-time job. Members of this last group, who usually work part time but who want full-time jobs and are available for full-time work, will be called *underemployed* in what follows.⁶ In November 2009, there were almost 8.9 million workers⁷ who were categorized as underemployed. (See chart 1.) In the fourth quarter of 2009, the average number of underemployed workers per month was greater in both absolute and relative (percent of the employed) terms than in any previous quarter in the past 61 years.

Those persons *not* active in the labor force are asked an additional set of questions about their current desire for employment, reasons for not looking for work, recent job search activities, and availability for work. Those who then report to the CPS interviewer that they want a job are classified as members of the *labor force reserve*.⁸ In its monthly report *The Employment Situation*, the Bureau of Labor Statistics presents a table showing the size of this group and refers to its members as "persons who currently want a job."⁹ In November 2009, there were about 5.6 million individuals who were classified as members of the labor force reserve. A subset of the labor force reserve is the group consisting of those who are marginally attached to the labor force: persons who have looked for a job sometime in the past 12 months and who were available to take a job.¹⁰ In November 2009, some 2.3 million individuals would have met the criteria for falling into the margin-

ally attached group.¹¹ The group represented about 41 percent of the members of the labor force reserve in November. In a previous analysis by Sum and Khatiwada of the likelihood that members of the labor force reserve and the marginally attached would be looking for work the next year, only small differences were found in their future jobseeking behavior.¹²

The findings of the monthly CPS can be used to estimate the combined pool of unutilized and underutilized workers (the unemployed, the underemployed, and the labor force reserve) in any given month or calendar quarter of the year. Estimates of the size of each of these three groups from the November 2009 CPS are displayed in chart 1. None of the estimates shown are seasonally adjusted, because what is sought is the actual total number of individual workers experiencing one of these three labor market problems in a given month. In November 2009, there were an estimated 14.4 million workers who were unemployed, yielding a seasonally unadjusted unemployment rate of 9.4 percent. As noted earlier, almost 8.9 million more persons were underemployed, working part time for economic reasons but desiring full-time jobs. These individuals represented approximately 6.4 percent of the employed in the Nation in November. Finally, an estimated 5.6 million individuals were members of the labor force reserve, wanting a job at the time of the survey but not actively looking for one. The total pool of unutilized and underutilized workers was about 28.9 million, yielding a labor underutilization rate of 18.2 percent, the highest since the bottom of the deep recession of 1981–82.

Trends and comparisons

The so-called Great Recession began in December 2007 and ended in June 2009, according to the National Bureau of Economic Research, the official arbiter of business cycle dating in the United States. As the following tabulation shows, during October–November 2007, the 2-month period preceding the onset of the recession, the number of underemployed workers in the United States was estimated to be slightly more than 4.2 million:¹³

<i>Period</i>	<i>Number underemployed</i>
October–November 2007	4,201,000
October–December 2008	7,217,333
October–December 2009	8,907,333
Absolute change, 2007–09	4,706,333
Percent change, 2007–09	112

During the fourth quarter of 2008, the number of underemployed jumped substantially, to 7.2 million, after which it rose further, to 8.9 million, in the fourth quarter of 2009. The absolute increase in the pool of underemployed workers over this 2-year period was 4.7 million, and the percent increase

Chart 1. Using monthly national CPS data to identify the number of unemployed and underemployed workers and members of the labor force reserve in November 2009 (numbers not seasonally adjusted and in thousands)

was 112 percent. Both figures were the largest in the country in any 2-year period since the end of World War II.

The CPS collects information from the underemployed on their reasons for being underemployed. The Bureau of Labor Statistics then combines these reasons into two main categories: slack work or business at their current firm or an inability to find a full-time job. Just prior to the onset of the recession, about 64 percent of the underemployed identified slack work as the primary reason for being underemployed while close to 30 percent cited an inability to find a full-time job. The following tabulation presents the change in the number of underemployed persons in the United States, by reason for underemployment, between October–November 2007 and October–December 2009:¹⁴

<i>Reason for underemployment</i>	<i>October–November 2007</i>	<i>October–December 2009</i>	<i>Absolute change</i>	<i>Percent change</i>
Total underemployed	4,201,000	8,907,000	4,706,000	112
Slack work or business at current firm or in current industry	2,786,000	6,530,000	3,744,000	134
Could not find full-time work	1,163,000	2,158,000	995,000	86

Over the past 2 years, both groups of underemployed workers have increased their numbers substantially, but the absolute growth and the rate of increase were greater among

those citing slack work at their firm or in the industry in which they work. These workers seemingly have jobs at which they usually would have worked full time, whereas those who said that they could not find full-time work appear to be in jobs for which part-time work is the norm. This is an important finding, because past research has shown that part-time workers typically receive far less training, both informal and formal, from their employers and receive a much lower rate of return in future wages from such work experience.¹⁵ Indeed, one study suggests that young women (20–34 years) receive a zero rate of return from part-time work experience.¹⁶

To place the steep increases in the number of underemployed during the recent recession into perspective, the following tabulation compares growth in their numbers (not seasonally adjusted) in comparable 2-year periods over the previous three recessions, in 2001, 1990–91, and 1981–82 (note that the definition of underemployment in the years prior to 1994 was less rigorous than the current definition):

<i>Recession</i>	<i>Two months prior to recession</i>	<i>Two years later</i>	<i>Absolute change</i>	<i>Percent change</i>
2007–09	4,201,000	8,684,000	4,483,000	107
2001	3,606,000	5,098,000	1,492,000	41
1990–91	4,650,000	6,167,000	1,517,000	33
1981–82	4,176,000	5,859,000	1,683,000	40

Although the previous two recessions lasted for a shorter period than the most recent one (9 months in 2001 and 10 months in 1990–91), the tabulation shows that the number of underemployed continued to rise for nearly 2 full years after the official end of the recession in all three cases. In addition, in each of the three previous recessions, the number of underemployed rose by 33 percent to 41 percent over the 2-year period following the recession, compared with an increase of 107 percent in the recession of 2007–09. The latter rate of growth in underemployment is unprecedented.

Another way of identifying the severity of underemployment is to calculate its relative incidence during a given period. An estimate of the incidence of underemployment is given by the ratio of the number of persons underemployed to the number employed in a given period. As the following tabulation indicates, in October–November 2009 the incidence of underemployment (not seasonally adjusted) was 6.3 percent, implying that between 6 and 7 of every 100 employed were underemployed (note that the published underemployment estimates for April–May 1983 and April–May 1992 were adjusted downward by 25 percent¹⁷ in order to make them compatible with the definitions of the underemployed that have been used by the Bureau of Labor Statistics since 1994):

<i>Period</i>	<i>Underemployment</i>	<i>Total Employment</i>	<i>Incidence of underemployment (percent)</i>
October–November 2009.....	8,684,000	139,110,000	6.3
January–February 2003.....	5,098,000	136,170,000	3.7
April–May 1992.....	4,625,000	118,082,000	3.9
April–May 1983.....	4,394,000	99,191,000	4.4

In November–December 2009, the incidence of underemployment rose further, to 6.6 percent. In the previous three recessions, the incidence of underemployment approximately 2 years after the beginning of the recession ranged from a low of 3.7 percent in the 2001 recession to a high of 4.4 percent in the 1981–82 recession. Clearly, the overall incidence of underemployment in the United States in October–November 2009 was substantially above its level in the previous three recessions.

Underemployment in the United States has been found to be cyclically sensitive over the past three decades. Under the BLS definition of underemployment that has been in place since 1994, the incidence of underemployment fell steadily from 3.8 percent in 1994 to 2.3 percent in 2000 as the national unemployment rate declined from 6.1 percent in 1994 to 4.0 percent at the end of the decade. (See chart 2.) During the recession of 2001 and the largely jobless

recovery of 2002–03,¹⁸ the underemployment rate rose to 3.4 percent, after which it fell back to 2.9 percent in 2006 following 3 consecutive years of job growth and declining unemployment. From 2007 on, however, the incidence of underemployment has more than doubled, rising to a new record high of 6.4 percent of the employed in the fourth quarter of 2009.

The sharp rise in the number of workers reporting being employed part time for economic reasons is due partly to reemployment difficulties that dislocated workers are having. Unemployed individuals who regain employment in the year after they were separated from their jobs frequently cite a reduction in hours relative to those worked on the job they previously held. A recent survey of the job search behavior and job-finding success of the unemployed found that 15 percent of the newly reemployed were working in a job that provided fewer hours than their former position did.¹⁹ Another analysis of the employment status of reemployed dislocated workers in the United States in January 2008 revealed that 8.5 percent of the reemployed were working part time for economic reasons.²⁰ The underemployment rates of these reemployed dislocated workers varied by age, educational attainment, and race or ethnicity, and were considerably higher for younger workers (20–24 years) and the oldest workers (65 years and older); those without postsecondary college degrees, especially high school dropouts; Blacks and Hispanics; and many service and blue-collar workers, including construction and extraction workers. The underemployment rates of service and construction workers were in the 13.3-percent to 13.6-percent range, compared with 10 percent for production workers and 4 percent for professional and management-related workers.

The underemployed and the Great Recession

Knowledge of which workers have been most adversely affected by the steep rise in underemployment over the past few years is indispensable in gauging the economic impacts of underemployment on U.S. workers. To identify the incidence of underemployment among key demographic, educational attainment, and industrial and occupational groups of workers in the Nation, the findings of the CPS monthly household surveys for the October–December periods of 2007 and 2009 were analyzed. The data were then used to estimate changes in the incidence of underemployment for each of these groups over the preceding 2-year period.

Table 1 displays findings on the incidence of underemployment across sex, age, and racial or ethnic groups

Chart 2. Underemployment as a percent of total civilian employment in the United States, selected years, 1994 to fourth quarter 2009

of employed U.S. workers over the aforesaid 2-year period. For all employed workers combined, the incidence of underemployment more than doubled over the period, rising from 3.0 percent in the fourth quarter of 2007 to 6.4 percent in the fourth quarter of 2009. Although men have experienced above-average rates of job loss and rising unemployment rates during the past 2-year period in question, both men and women encountered nearly identical rates of underemployment in the fourth quarter of 2009, 6.5 percent and 6.4 percent, respectively.

Workers in nearly every major age group and racial or ethnic group saw their underemployment rates more than double over the 2 years examined, but large differences remained across groups at the end of 2009. Young adults (20–24 years) and teenagers (16–19 years) faced the highest rates of underemployment; nearly 11 percent of employed 20- to 24-year-olds were underemployed. (See table 1.) The underemployment rates of workers other than young adults declined steadily with their age, falling to 7.7 percent for 25- to 29-year-olds, to below 6 percent for 35- to 54-year-olds, and to a low of 3.6 percent for those 70 years and older. The Nation's young adults were nearly 3 times as likely to be underemployed in the fourth quarter of 2009 as the oldest group of workers.

Underemployment rates also doubled for employed members of each racial or ethnic group over the 2-year

period shown, but again, large disparities in the incidence of underemployment remained at the end of 2009. (See table 1.) Underemployment rates were lowest among Asians (4.7 percent) and White non-Hispanics (5.2 percent), rose to 7.5 percent for Black non-Hispanic workers, and peaked at 12.0 percent for Hispanics. Thus, Hispanic workers faced underemployment rates that were more than 2½ times as high as those of Asians and Whites. As will be revealed subsequently, the high share of Hispanic workers with no postsecondary schooling and the elevated incidence of underemployment faced by Hispanic workers with limited formal schooling are responsible for these large gaps in overall underemployment rates between Hispanics and their Asian and White non-Hispanic peers.

The incidence of underemployment among U.S. workers by their school enrollment and educational attainment is displayed in table 2. Employed adults 16 to 24 years old and still enrolled in school are identified separately from those in that age group who are employed but not enrolled in school.²¹ Those young adults who are not enrolled in school and all adults 25 years and older were assigned to one of five educational attainment categories, ranging from those lacking a regular high school diploma or a General Education Development (GED) certificate to those holding a master's or higher academic degree.

All seven educational attainment groups of workers

Table 1. Incidence of underemployment among employed workers 16 years and older, by sex, age, and race or ethnicity, October–December 2007 to October–December 2009

[In percent]

Category	October–December 2007	October–December 2009	Percentage-point change
All employed workers	3.0	6.4	3.4
Men.....	3.0	6.5	3.4
Women.....	2.9	6.4	3.5
Age, years			
16–19	4.9	9.4	4.5
20–24	5.2	10.6	5.4
25–29	3.7	7.7	4.0
30–34	2.9	6.7	3.8
35–44	2.5	5.8	3.3
45–54	2.5	5.6	3.1
55–64	2.3	5.2	2.9
65–69	2.4	4.6	2.2
70 and older	1.6	3.6	2.0
Race or ethnicity			
Asian.....	1.8	4.7	2.9
Black non-Hispanic	3.8	7.5	3.7
Hispanic	5.0	12.0	7.0
White non-Hispanic.....	2.5	5.2	2.7

shown in table 2 saw their underemployment rates more than double over the past 2 years, but the absolute percentage-point increases varied widely across the five educational groups not enrolled in school. In the fourth quarter of 2009, the incidence of underemployment ranged from a high of 16.4 percent among high school dropouts, down to 8.4 percent for high school graduates, and on to a low of 2.2 percent for those employed adults with a graduate school degree. In the fourth quarter of 2009, employed high school dropouts were 7.5 times as likely to be underemployed as their contemporaries with an advanced degree and high school graduates were 2.4 times as likely to be underemployed as their peers with a bachelor's degree. Gaps in underemployment rates across educational groups were greater than those for unemployment rates.

To afford a greater insight into how educational attainment influences underemployment rates for different demographic subgroups, a matrix of underemployment rates by educational attainment was constructed for each racial or ethnic group, for the five groups of workers not enrolled in school.²² (See table 3.) For all four racial or ethnic groups, the incidence of underemployment fell steadily and strongly with their level of educational attainment in the fourth quarter of 2009. High school

dropouts in each racial or ethnic group faced double-digit underemployment rates, with the underemployment rates for Black and Hispanic dropouts falling into the 17- to 19-percentage-point range. At the top of the educational distribution (those with a master's or higher degree), underemployment rates fell into the 1- to 3-percent range.

For each of the four racial or ethnic groups, employed high school dropouts were almost 6 to nearly 10 times more likely to face underemployment problems than their peers with an advanced degree. Across the 20 educational attainment and racial or ethnic groups, the incidence of underemployment ranged from lows of 1.2 percent and 2.2 percent among Asian and White advanced degree holders, respectively, to a high of 19.3 percent among Hispanic high school dropouts. The relative size of the difference between the incidence of underemployment among the top and bottom groups was 16 times.

The monthly CPS also collects information on employers of the workers, their types of businesses, and the occupational titles of the workers' jobs. This information was used by the Bureau of Labor Statistics to assign the workers into 21 industrial sectors and 24 major occupational groups. Table 4 shows the underemployment rates of workers in the fourth quarters of 2007 and 2009 for the 7 industrial sectors with the highest and lowest underemployment rates in the fourth quarter of 2009, as well as for 7 selected other sectors (including both du-

rable and nondurable manufacturing).

Underemployment rates rose in all 21 industrial sectors—indeed, at least doubling in all but 4 of them—over the 2-year period examined. Still, in the fourth quarter of 2009, large differences existed in the magnitude of underemployment across these industries. In the bottom 7 industries, the average (unweighted) underemployment rate was 2.6 percent, while the average underemployment rate at the top was 11.9 percent. The individual underemployment rates for these sectors ranged from lows of 1.1 percent and 1.3 percent for utilities and public administration, respectively, to highs of 13.6 percent in construction and 19.3 percent in private household work. Many of the industries with below-average underemployment rates experienced either below-average declines in employment (utilities, government) or increases in employment (educational services) over the past 2 years, while some of those in the top 7 industries (retail trade, construction) had above-average declines in employment. Yet, some industries, such as accommodation and food services, had much higher underemployment growth than would have been expected on the basis of their employment decline. Deep downsizing in manufacturing industries, in contrast, seems to have been accompanied primarily by layoffs rather than a large shift to underemployment.

The underemployment rates of workers in 24 major occupational groups in the fourth quarters of 2007 and 2009 also were calculated. Findings for the top 7 and bottom 7 occupational groups, as well as for 10 selected other oc-

cupational groups, are displayed in table 5. Workers in all 24 of these occupational groups saw their underemployment rates rise over the 2-year period studied, and the incidence of underemployment at least doubled for about two-thirds of the 24 groups.

At the end of the period, underemployment rates ranged widely across the occupational groups shown. The seven groups with the lowest underemployment rates had a mean (unweighted) rate of only 2 percent, compared with a mean of 11.6 percent for the top seven occupa-

tional groups. Across individual occupational groups, the underemployment rates ranged from lows of 1.3 percent to 1.5 percent for protective service, computer and mathematical, and legal occupations to 14 percent to 15 percent for building and grounds cleaners, food preparation and serving, and construction and extraction occupations. Workers in the latter three occupations had underemployment rates 10 times as high as those in the bottom three groups. Overall, professional workers dominated the list of occupations at the bottom of the distribution while service and construction workers dominated at the top.

A separate multivariate analysis based on binary logit regression models of the underemployment status of U.S. workers employed in the fourth quarter of 2009 found that the probability of underemployment among men and women was significantly associated with their age, racial or ethnic group, educational attainment, and occupational attachment, as well as with the unemployment rate of the State in which they resided.²³ Younger workers (under 25 years), Blacks and Hispanics, recent immigrants, high school dropouts and high school graduates with no post-secondary schooling, many service workers, and blue-collar workers were significantly more likely to be underemployed, as were those living in States with above-average unemployment rates. The predicted probability of underemployment among four hypothetical women in the fourth quarter of 2009 ranged from a low of 1 percent among older White women with a master's degree in a management occupation and living in a State with a below-average unemployment rate to a high of 50 percent for a young Hispanic immigrant lacking a high school diploma and working in a food preparation occupation in a State with a high unemployment rate.

Weekly hours of work and hourly wages

Earlier, the underemployed were defined as those workers who are working part time (less than 35 hours a week) but who both want and are available for full-time work. The CPS labor force questionnaire collects data on actual weekly hours worked by the employed and their hourly or weekly wages.²⁴ How many hours do the underemployed actually work per week? How do their hours of work compare with those of the full-time employed in similar educational groups? An analysis of the findings of the October–December 2009 CPS addresses these questions.

The weekly hours of work of the underemployed varied considerably in the last quarter of calendar year 2009. The following tabulation, from the October–December 2009 CPS public-use files, shows that slightly under 10 percent of the underemployed worked less than 10 hours per week, another 19 percent worked from 10 to 19 hours,

Table 5. Incidence of underemployment among employed workers 16 years and older, by occupational group, October–December 2009, seven lowest, seven highest, and selected other groups

39 percent worked between 20 and 29 hours, and the remaining one-third worked between 30 and 34 hours:

<i>Weekly hours worked</i>	<i>Percent of underemployed working those hours</i>
1–9	9.1
10–19	18.6
20–24	24.0
25–29	14.9
30–34	33.4
Median	24.0
Mean, underemployed	22.5
Mean, full-time workers	44.2

As the tabulation shows, the median number of weekly hours of work was 24 hours, the mean, 22.5 hours. In the fourth quarter of 2007, the mean was a slightly higher 23.3 hours. In contrast, the mean number of weekly hours of work among the full-time employed was 44.2 hours, nearly twice as high as that for the underemployed. Clearly, on average, underemployment generates a substantial loss in weekly hours of work and, hence, in the weekly earnings of those working part time for economic reasons. Their sharply reduced aggregate hours of work also lower the real output of the U.S. economy and increase the size of the gap between potential and actual output (gross domestic product, or GDP).

The mean number of weekly hours of work among the underemployed in the fourth quarter of 2009 varied modestly across educational groups. (See table 6.) Workers in 4 of the 5 education groups listed had between 22 and 23 mean weekly hours of work, while those with a master's or higher degree averaged just under 21 hours. On average, underemployed members of each educational group worked substantially fewer hours per week than their full-time peers. The gaps in mean weekly hours of work tended to rise with educational attainment, increasing from just under 20 hours for high school dropouts to more than 25 hours for those with master's or higher academic degrees.

The mean hourly earnings of the underemployed also were comparatively low, on average, and rose modestly with educational attainment up through the bachelor's degree level. (See table 7.) The mean hourly wages for all underemployed workers was \$12.80. Among those not enrolled in school, mean hourly wages ranged from a low of \$11.23 for high school dropouts, to \$11.78 for high school graduates, to \$14.35 for bachelor's degree holders, to a high of \$21.46 for those with a master's or higher degree. Underemployed workers with a bachelor's degree made \$3.12 more per hour than high school dropouts.

The mean hourly earnings of the underemployed were considerably below those of full-time workers, both overall and in each educational group. The mean hourly earnings for full-time wage and salary workers were \$20.96, exceeding those of the underemployed by \$8.16, or 64 percent. In each of the five education groups whose members were not enrolled in school, mean hourly earnings of the underemployed were anywhere from 88 cents to \$11.82 below those of their full-time employed peers. Although part of these wage differentials are attributable to the higher mean amount of work experience among the full-time employed, a large number of the underemployed, especially bachelor's degree holders, seem to suffer from so-called malemployment, in which their jobs do

Table 6. Gaps between mean number of weekly hours worked by full-time employed and underemployed persons, by educational attainment, fourth quarter, 2009

All workers.....	44.2	22.5	21.7
High school dropouts	42.6	22.9	19.7
High school graduates ¹	43.6	22.8	20.8
1–3 years of college ²	43.9	22.6	21.3
Bachelor's degree	44.7	22.0	22.7
Master's or higher degree.....	46.4	20.9	25.5

¹ Including those who received a General Education Development (GED) certificate.
² Including those who received an associate's degree.

not utilize the education and occupational skills that they possess. The weekly earnings losses from underemployment thus stem from both sharply lower weekly hours of work and lower hourly wages from being employed in less skilled, lower paying occupations.

Underemployment by household income

The preceding findings on the sharply higher incidence of underemployment among less educated workers, especially Black and Hispanic workers,²⁵ those in many lower skilled occupations, and those in lower wage occupations, suggest that underemployment tends to be more highly concentrated among workers from lower income households. To more rigorously assess the incidence of underemployment among workers in different household income groups, the findings about the household income distribution from the March 2009 CPS work experience and income supplement were combined with the findings about the distribution of the underemployed by their position in the household income distribution (classified by deciles) from the October–December 2009 monthly CPS surveys.

The March CPS survey questionnaire contains a work experience and income supplement that collects information on each working-age respondent's employment, annual earnings, and income experiences in the previous calendar year. The annual incomes, including cash transfers and property income, of all household members are combined to estimate the annual pretax money income of the household. Each household was ranked by the size of its annual income, and the cutoff points were calculated for

Table 7. Mean hourly wages of underemployed persons and full-time wage and salary workers, 16 years and older, by educational attainment, October–December 2009 averages

[In current dollars]

Education group	Underemployed	Full-time workers	Difference
All workers	\$12.80	\$20.96	\$8.16
High school students	7.07	8.20	1.13
College students	13.04	12.67	–.37
High school dropouts	11.23	12.11	.88
High school graduates ¹	11.78	16.67	4.89
1–3 years of college ²	13.83	18.96	5.13
Bachelor's degree	14.35	26.17	11.82
Master's or higher degree	21.46	32.07	10.61

¹ Including those who received a General Education Development (GED) certificate.² Including those who received an associate's degree.

each decile (10 percent) of the income distribution. The bottom decile included all households with annual incomes at or below \$12,160, while the top decile comprised all households with pretax annual incomes above \$133,300.

The monthly CPS labor force questionnaire asks the respondent to provide an estimate of the household's gross money income in the previous 12-month period. For this article, each person who was employed in the October–December 2009 period was assigned to the 2008 household income decile that came closest to matching that person's household income reported in the 2009 CPS interview.²⁶ The following tabulation displays the resulting estimates of the incidence of underemployment in each household income decile during the October–December period of 2009:²⁷

<i>Income decile</i>	<i>Percent underemployed</i>
Lowest	20.6
Second	17.2
Third	12.7
Fourth	8.3
Fifth	6.1
Sixth	5.4
Seventh	4.4
Eighth	3.6
Ninth	2.5
Highest	1.6
Missing income	5.3

As the tabulation shows, the incidence of underemployment among the employed varied widely across the 10 household income deciles, falling steadily and steeply as the income position of the household improved. More than 20 percent of the employed in the bottom decile of the income distribution were underemployed, as were 17 percent of those in the second-lowest decile. The incidence of underemployment fell into the 5-percent to 6-percent range for those in the middle two deciles and declined to lows of 2.5 percent and 1.6 percent for workers living in households in the top two income deciles. The incidence of underemployment in the fourth quarter of 2009 was 13 times higher among those workers in the bottom income decile than among those in the top decile (20.6 percent, as opposed to 1.6 percent). These findings clearly reveal that the economic costs of underemployment are disproportionately borne by workers at the lower end of the income distribution; thus, underemployment contributes in an important way to the high and rising degree of income inequality in the United States.

Costs of underemployment

Empirical research on the size of the Nation's GDP gap since Arthur Okun's early work in the 1960s²⁸ has attempted to estimate the output losses associated with reduced hours of work as the economy moves away from full employment. The foregoing findings on the number of underemployed workers, their reduced mean weekly hours of work, and their hourly earnings can be combined to provide a set of estimates of the aggregate annualized earnings losses associated with the higher (excess) levels of underemployed U.S. workers in the fourth quarter of 2009. During that quarter, there were an estimated 8,907,000 underemployed workers per month in the United States, on average.²⁹ The mean number of actual weekly hours worked by this group of underemployed workers was estimated at 22.5 hours. During the same period, the full-time employed reported working 44.2 hours per week. The gap between the mean weekly hours of these two groups of workers was a sizable 21.7 hours per week. For every hour worked by the underemployed, the mean gross hourly wage was estimated to be \$12.83, well below the average of the full-time employed. Multiplying the lost 21.7 hours of work by the \$12.83 hourly wage yields an estimate of about \$278 per week for the mean lost weekly earnings of the underemployed. This figure is equivalent to an estimated annualized loss in gross earnings of \$14,456. Note that turnover in the ranks of

the underemployed during the year will cause the number of underemployed to substantially exceed 9 million for the year. (The preceding discussion assumes that turnover throughout the year will leave the mean weekly earnings loss unchanged.)

The aggregate annualized loss in gross earnings due to the excess level of underemployment in the fourth quarter can be generated by multiplying the \$14,456 figure by the 4,706,333 excess number of underemployed workers. This excess level of underemployment represents the difference in the number of underemployed workers between the fourth quarters of 2007 and 2009, and yields an aggregate value of slightly more than \$68 billion dollars in lost earnings. In addition to the lost gross earnings of the underemployed themselves, other losses to society include less payroll taxes paid by employers and lower nonwage compensation paid to the underemployed in the form of vacation pay, health insurance benefits, and pension contributions. The Social Security taxes paid by employers alone would account for another 7.6 percent of the lost gross earnings of the underemployed, and lost unemployment insurance taxes, disability contributions, and employee benefits would likely account for another 7.4 percent to 7.5 percent of their earnings. A conservative estimate is that the combined loss of payroll taxes and nonwage employer contributions would amount to about 15 percent of the gross pretax lost earnings of the Nation's underemployed. All told, the combined aggregate annualized earnings, payroll tax, and other nonwage compensation losses associated with higher levels of underemployment are an estimated \$78 billion dollars.

Besides receiving sharply lower hours of work per week and lower weekly earnings, the underemployed are considerably less likely than their full-time employed counterparts to receive key employee benefits from their employers, such as health insurance and pension coverage.³⁰ Findings of the March 2009 CPS work experience and income supplement were used to generate estimates of the health insurance coverage of the underemployed and their receipt of health insurance and pension benefits from their employers. In 2008,³¹ 27 percent of the underemployed reported receiving health insurance coverage from their employer. (See table 8.) The likelihood of such employer-financed coverage rose with the workers' level of formal schooling, up to the level of postsecondary schooling.

Sixty percent of the underemployed had some form of health insurance (not necessarily from the employer), including Medicaid and Medicare. Coverage rose steadily with the level of formal schooling: eighty-two percent of

Table 8. Health insurance coverage and pension plan coverage of the underemployed 16 years and older, by educational attainment, March 2009

[In percent]

Education group	Receives health insurance coverage from employer	Has some type of health insurance coverage	Has pension plan coverage

² Including those who received an associate's degree.
 SOURCE: March 2009 CPS survey, public-use files, tabulated by authors.

those with a master's or higher degree had health insurance, compared with 40 percent of high school dropouts. Twenty-eight percent of the underemployed reported that they were eligible for a pension plan at work. Again, the fraction reporting some pension coverage rose steadily with the level of schooling: thirty-nine percent of those with a postbaccalaureate degree participated in a pension plan, compared with 14 percent of high school dropouts.

Underemployed workers suffer other important losses, including less training provided by employers to part-time workers, a lower return to future wages from part-time employment today, and lower future earnings. Their lost earnings today reduce their consumption of goods and services, thereby holding down spending, output, and employment in other sectors of the economy. Also, their lower incomes and expenditures reduce their tax contributions to the Federal and State government in the forms of Federal and State income taxes, State sales taxes, and lower Social Security payroll taxes, thereby increasing Federal and State budget deficits. Finally, the lower income groups of underemployed workers especially are more likely to depend on in-kind transfers such as food stamps, rental subsidies, and Medicaid to support themselves and their families, thereby imposing fiscal costs on the rest of the taxpaying public. □

Notes

¹ The National Bureau of Economic Research, the Nation's arbiter of the beginning and ending dates of recessions, has designated the recent recession as having lasted from December 2007 to June 2009.

² For an overview of the labor market impacts of the Great Recession of 2007–09, especially on blue-collar workers and men, see "The Trap," *The Economist*, Jan. 16, 2010, p. 32; Katherine Klemmer, "Job availability during a recession: an examination of the number of unemployed persons per job opening," *Issues in Labor Statistics*, Summary 10–03 (U.S. Bureau of Labor Statistics, March 2010); Andrew Sum, Paul Harrington, Ishwar Khatiwada, Joseph McLaughlin, and Sheila Palma, *The Deep Depression in Blue Collar Labor Markets in the U.S.: Their Implications for Future Economic Stimulus and Workforce Development Policies* (Boston, Northeastern University, Center for Labor Market Studies, December 2009); and Andrew Sum, Allison Beard, Joseph McLaughlin, and Ishwar Khatiwada, *The Labor Market Impacts of the Great Recession of 2007–2009: Impacts on Unemployment and Labor Underutilization* (Boston, Northeastern University, Center for Labor Market Studies, 2009).

³ The term "labor underutilization" refers to a combination of problems associated with open unemployment, hidden unemployment, and underemployment. (The open unemployed are those who meet the official BLS definition of unemployment; the hidden unemployed are those persons who, at the time of the CPS, are not active in the labor force and who express a desire for immediate employment.) For a review of labor underutilization problems among teens, young adults, and older adults in the United States in recent years, see Andrew Sum, Ishwar Khatiwada, Joseph McLaughlin, and Sheila Palma, *The Lost Decade for Teen and Young Adult Employment in Illinois: The Current Depression in the Labor Market for 16–24 Year Olds in the Nation and State*, report prepared for the Chicago Alternative Schools Network (Boston, Northeastern University, Center for Labor Market Studies, January 2010); and Sum, Beard, McLaughlin, and Khatiwada, *The Labor Market Impacts*.

⁴ The CPS does interview members of some group quarters, such as college dormitories and boarding schools, but does not interview persons residing in institutions (for example, jails, prisons, or nursing homes), members of the Armed Forces, or the homeless.

⁵ The seasonally adjusted unemployment rate was 10.0 percent in November 2009. (See *The Employment Situation: November 2009*, (U.S. Bureau of Labor Statistics, Dec. 4, 2009).)

⁶ The Bureau of Labor Statistics changed the definition of underemployment in 1994 with the introduction of a new labor force questionnaire. For a review of changes in the basic CPS labor force questions in 1994, including the revision in the procedures for estimating those persons employed part time for economic reasons, see John E. Bregger and Cathryn S. Dippo, "Overhauling the Current Population Survey: Why is it necessary to change?" *Monthly Labor Review*, September 1993, pp. 3–9; and Anne E. Polivka and Jennifer M. Rothgeb, "Overhauling the Current Population Survey: Redesigning the CPS Questionnaire," *Monthly Labor Review*, September 1993, pp. 10–28.

⁷ Not seasonally adjusted.

⁸ In his 1979 book on the changing quality of jobs in the United States, Eli Ginzberg referred to this group of persons wanting jobs as the labor force overhang. (See Eli Ginzberg, *Good Jobs, Bad Jobs, No Jobs* (Cambridge, MA, Harvard University Press, 1979).)

⁹ The CPS interviews a household eight times over a 16-month period. Those interviewed for the first time, say, in January 2009 will be reinterviewed in February–April 2009, dropped for 8 months, and then reinterviewed in January–April 2010. The job search behavior of

the labor force reserve may then be tracked the next year.

¹⁰ See *The Employment Situation*, table A-13 (U.S. Bureau of Labor Statistics, November 2009). In a recent article, the marginally attached are described as those "who have simply given up looking" for work ("The Man Who Fell to Earth," *The Economist*, Jan. 23–29, 2010, p. 17.)

¹¹ The 2.3 million figure represents an increase of 1 million over the number of marginally attached in November 2007, right before the onset of the recession.

¹² See Andrew Sum and Ishwar Khatiwada, *Labor Underutilization Impacts of the Great Recession of 2007–2009: Variations in Labor Underutilization Problems Across Age, Gender, Race-Ethnic, Educational Attainment and Occupational Groups in the U.S., 2009 Fourth Quarter*, working paper (Boston, Northeastern University, Center for Labor Market Studies, March 2010).

¹³ The numbers of underemployed shown in the tabulation are not seasonally adjusted and are on the Internet at www.bls.gov/webapps/legacy/cpsatab8.htm (visited Nov. 19, 2010).

¹⁴ The numbers of underemployed shown in the tabulation are not seasonally adjusted and are on the Internet at www.bls.gov/webapps/legacy/cpsatab8.htm (visited Nov. 19, 2010).

¹⁸ Payroll employment in the United States did not begin to register steady growth until the fall of 2003, nearly 2 years after the official end of the recession in November 2001.

¹⁹ See Debbie Borie-Holtz, Carl Van Horn, and Cliff Zukin, *No End in Sight: The Agony of Prolonged Unemployment* (New Brunswick, NJ, Rutgers University, John N. Heldrich Center for Workforce Development, May 2010).

²⁰ See Andrew Sum, Ishwar Khatiwada, and Mykhaylo Trubskyy, *The Dislocation Experiences and Post-Dislocation Employment and Weekly Earnings Outcomes of U.S. Workers, 2005–2007* (Boston, Northeastern University, Center for Labor Market Studies, 2010). The report's findings are based on the January 2008 CPS supplement on dislocated workers.

²¹ The monthly CPS questionnaire collects school enrollment information only from persons 16 to 24 years old. The October CPS contains a supplement that collects school enrollment information on all persons 3 years and older.

²² As noted earlier, adult workers 25 years and older who were enrolled in college are included in the table.

²³ See Andrew Sum and Ishwar Khatiwada, with Sheila Palma, *Underemployment Problems in U.S. Labor Markets in 2009: Predicting the Probabilities of Underemployment for Key Age, Gender, Race-Ethnic, Educational, and Occupational Subgroups of U.S. Workers* (Boston, Northeastern University, Center for Labor Market Studies, February

2010).

²⁴ Data on hourly or weekly earnings are collected only for wage and salary workers. One-fourth of the sample is used each month.

²⁵ Among both high school dropouts and high school graduates with no completed years of postsecondary schooling, the incidence of underemployment was considerably greater among Blacks and Hispanics than among Asians or White non-Hispanics in the fourth quarter of 2009. Racial and ethnic gaps in underemployment were much smaller for the most well educated.

²⁶ Monthly CPS data on household income are reported in categorical form by the respondent, rather than calculated by the U.S. Census Bureau by adding all money incomes reported by each household member.

²⁷ Note that the employed are not distributed proportionately across the 10 household income deciles: a below-average number of

employed persons populate the bottom two deciles, an above-average number the higher deciles.

²⁸ See, for example, Arthur M. Okun, *The Political Economy of Prosperity* (New York, W. W. Norton and Company, 1970), in which the author discusses his earlier work on estimating the GDP gap in the 1960s; and Alan L. Sorkin, *Monetary and Fiscal Policy and Business Cycles in the Modern Era* (Lexington, MA, Lexington Books, 1988).

²⁹ The figures that follow in this paragraph and the next are not seasonally adjusted.

³⁰ Similar findings appear to apply to paid sick leave in the United States. (See, for example, James Warren, "Cough if You Need Sick Leave," *Bloomberg Business Week*, June 7–13, 2010, p. 33.)

³¹ In the March 2009 CPS supplement, the questions on health insurance and pension coverage are asked of the longest job held during the past year.

Reversals in the patterns of women's labor supply in the United States, 1977–2009

Despite strong increases in women's labor force participation—especially among married women with children—in the 1980s, and somewhat less strong increases in the 1990s, the first decade of the twenty-first century has seen declines across the board; these have been especially marked among single women, women with no children, and women with more than 16 years of education

Diane J. Macunovich

Most analyses of women's labor force participation in the past 15 years or so have focused on married women. The labor force participation rate of this group increased dramatically in the 1970s and 1980s, as reported by Marisa DiNatale and Stephanie Boraas,¹ and Chihui Juhn and Simon Potter,² among many others. But the labor force participation of married women—especially those with children—increased only marginally in the 1990s, and began to decline toward the end of that decade. For married women with children, for example, the rate increased from 39.7 percent in 1970 to 66.3 percent in 1990, but then to only 70.6 percent in 2000; the rate was 69.3 percent in 2007. For married mothers with infants, the rate peaked in 1997, at 59.2 percent, and declined to 53.5 percent by 2005.³

The decline in married women's labor force participation in the last decade has been chronicled anecdotally in the popular press, where reporters tend to refer to it as the “opt-out revolution.”⁴ Claudia Wallis noted that opting out appears to occur more often among professional and managerial women, for whom “higher incomes permit more choices.”⁵ Similarly, Katharine Brad-

bury and Jane Katz found that declines in labor force participation were highest among highly educated women and married women with young children and high-earning husbands.⁶ Opting out is also evidenced by Linda Hirshman's survey of women whose marriages were reported in *The New York Times*, which showed that “half the wealthiest, most-privileged, best-educated females in the country stay home with their babies rather than work in the market economy.”⁷ Similarly, Claire Shipman and Katty Kay suggest that a revolution is occurring among professional women in which employers accede to more flexible work schedules for working mothers.⁸

Such a revolution seems to be consistent with other observed trends. Using the results of four large social surveys covering the years 1976–98, Arland Thornton and Linda Young-DeMarco found that, compared with young Americans in the 1970s, “young Americans in the 1990s were more committed to the importance of a good marriage and family life.”⁹ They found that agreement with the statement that there are “more advantages to being single than married” declined from 23 percent among women and 34 percent among men in 1980, to 11 per-

Diane J. Macunovich is a professor at the University of Redlands and an economist with the Institute for the Study of Labor (IZA). Email: diane_macunovich@redlands.edu

cent and 12 percent, respectively, in 1993. They concluded that, “although marriage became more optional and was perceived as more restrictive between 1957 and 1976, these trends do not seem to have continued into the 1980s and 1990s.” And Saul D. Hoffman, looking at female labor force participation between 1984 and 2004, found that, while fertility among 20- to 24-year-olds fell by 3.3 percent between 1993 and 2004, fertility rose by 20 percent for women aged 30–34 and by 44 percent for women aged 35–39.¹⁰ He found that, whereas single women with children were more likely to work in 2004 than in 1984, married women with children were less likely to do so. DiNatale found that workers in 1999 were more likely to prefer alternative work arrangements (contract, on-call, or temporary work) than workers in the mid-1990s.¹¹

But more recent work, such as that of Joan C. Williams, objects to the notion that opting-out is a voluntary phenomenon. Her work documents many cases in which women have been “pushed out by workplace inflexibility, failures of public policy [the lack of adequate childcare], and workplace bias,” referring even to some of the women mentioned in Lisa Belkins’ earlier “opting-out” article.¹² Williams maintains that opting out arises from “systemic discrimination” rather than from mothers’ own choices. Wallis states, “. . . a reluctant revolt is under way. Today’s women execs are less willing to play the juggler’s game.”¹³ Still, Williams states that “highly educated women are more—not less—likely to remain in the labor force than other women.”

Heather Boushey maintains that the notable declines in the labor force participation of mothers with children are due largely to cyclical economic conditions, with women becoming unemployed in the 2001 recession and choosing to become “discouraged workers” who stay at home with children rather than search for elusive employment.¹⁴ This hypothesis is hard to justify, however, in light of the fact that women’s labor force participation rates began to decline before 2000. For women aged 25–34 the decline began in 1998 or 1999, whereas for women aged 35–44, it began in 1997. For women with children under age 3, it began in 1998.¹⁵ In addition, Boushey’s claim is contradicted by evidence from survey data reported by Louise Story, who found that young women at elite colleges “say they have already decided that they will put aside their careers in favor of raising children.”¹⁶ Similarly, James P. Vere, using a cohort analysis rather than a time-series analysis, found that “the women of Generation X are not only having more children than women from the baby boom generation but are also supplying fewer hours to the labor market.”¹⁷ He found that this phenomenon ap-

pears not to be simply an effect of timing, since the mean number of children that these women reported they desire was 34 percent larger than the mean number of children that women born in 1956 or 1957 reported desiring when they were the same age. Vere states that, “if the trends reflect differences across cohorts, then the recent decline in female labor force participation in the United States is only the tip of the iceberg, and female labor force participation will fall even further as women of the baby boom generation—now in their 40s and 50s—retire from the labor force.”

Williams emphasized that the trend of opting out—whatever its causes—has been misrepresented because many of these women work fewer hours when they return to the labor force: “Women who work part time [in the United States] earn 21 percent less per hour than full timers. . . . On average, people who work 44 hours per week in the United States earn more than twice what those working 34 hours per week earn.”¹⁸ And she cited a study by the Wharton Center for Leadership and Change which found that, “while 70 percent of those surveyed reported feeling positive about their decisions to leave the labor force, 50 percent felt ‘frustrated’ when they tried to return to work, and 18 percent became ‘depressed.’” In addition, Golden reported that, in order to obtain flexible work schedules, women must often accept either an increase in working hours, an evening shift, or a switch to part-time status.¹⁹ Accepting one of these choices can often entail considerable hardship.

Thus, it is important to use data that are as comprehensive as possible to study the trend of opting out. What are its long-term implications? According to its intermediate projection, the Board of Trustees of OASDI expects that the overall women’s labor force participation rate will increase from the 2007 level of 59.3 percent to a level of 60.4 percent by 2083.²⁰ This projected increase implies a continued increase in the participation rate of married women, so it is important to examine recent trends to try to determine underlying causation. Do the most recent declines signify the beginning of a trend—or are they simply, as some have speculated, a temporary effect brought on by the business cycle?

There have been a number of studies that have examined econometrically the rise in women’s labor force participation before 2003 but have not discussed possible changes occurring after the mid-1990s. Francine Blau and Lawrence M. Kahn used Current Population Survey (CPS) data to focus primarily on the elasticity of hours worked by women aged 25–54 with respect to their own wages and the elasticity with respect to their husbands’ wages,

finding a sharp decline from the 1979–81 period to the 1989–91 period that attenuated during the 1990s.²¹ They also found a pronounced rightward shift of the labor supply function in the 1980s, but little change in the 1990s. In addition, Blau and Kahn's research indicates that the increase in hours worked that occurred during the 1990s was smaller than that which occurred during the 1980s. They indicated that little of this slowdown in the growth of hours worked could be traced to a change in wages, since real wages actually increased in that decade.

Bradley T. Heim also used the CPS and examined elasticity of labor force participation among married women aged 25–55 between 1979 and 2003, finding declines in elasticity similar to those found by Blau and Kahn.²² But like Blau and Kahn, Heim did not specifically note differences that occurred in the late 1990s. His graphs of annually estimated elasticity of labor force participation with respect to income, however, indicate a slight increase in the absolute value of the elasticity that began in the late 1990s, suggesting that women in this period became more responsive to changes in their nonlabor income (typically the husband's income, which Heim included in his non-wage income category). If women did become more responsive to changes in their nonlabor income, it would suggest that declines in participation in this period were driven at least in part by increases in husbands' wages.

Heim also attempted to estimate the proportion of each measured change in elasticity that was due to simple changes in the demographic characteristics of the women in the samples, that is, changes in the age composition of the sample as baby boomers aged, changes in education levels, or changes in the number of children. He found that, in fact, the declines in elasticity would have been even greater had demographic characteristics not shifted. Thus, the changes in elasticity must be due to something other than demographic factors.

Interestingly, Kelly Bishop, Bradley Heim and Kata Mihaly conducted a similar type of analysis for single women and found similar declines in elasticities between 1979 and 2003—and here again, the elasticity of participation with respect to income showed a slight increase in absolute value in the late 1990s.²³ In addition, the elasticity of hours worked with respect to income also showed a slight increase in that period.

Three studies—by Julie L. Hotchkiss, Heather Boushey, and Saul D. Hoffman—focus specifically on the change in labor force participation that has occurred since the mid-1990s. Hotchkiss used CPS data for all women aged 25–54 between 1975 and 2005, and found that in the 2000–05 period the positive effect of education on labor

force participation declined, and that the negative effect of unemployment on labor force participation declined as well. She calculated that, even if the unemployment rate had remained at its prerecession level, women's labor force participation “would still be significantly lower [in 2005] than it was in 2000.”²⁴ Her findings appear to contradict those of Boushey, who found that “the business cycle penalty is significantly greater in 2004 than in 2000 for all educational groups except for women with advanced degrees and either young or older children and women with less than a high school degree and any children.”²⁵ Hotchkiss found that the greatest contributor to the observed decline in women's labor force participation between 2000 and 2005 was “unobservables,” which by definition cannot be identified or forecast.

Boushey, using the logit function on data on women aged 25–44 in CPS outgoing rotation groups²⁶ from the 1984–2004 period, focused on the possible effect of the presence of children on women's labor force participation during this period and found a declining “child penalty.” Further analysis led Boushey to hypothesize that the decline in labor force participation rates during this period was a result of the 2001 recession; however, this hypothesis results from the use of year dummies rather than actual unemployment rates. And as pointed out earlier, this supposition does not explain why the decline began, for nearly all groups, before 2001. Boushey's finding is supported to some extent by Hoffman, who, in one of his models, used the same data and specification as Boushey. He also found a decreasing negative effect over time of children on mothers' labor force participation.²⁷

However, when marriage–year interaction terms were added to Boushey's specification, Hoffman found that, although the negative effect of marriage declined from 1984 through 1993, it then increased from 1993 to 2000 and again from 2000 to 2004. Hoffman calculated that, by 2004, the negative effect of marriage was nearly as large as it had been in 1984, even after controlling for the year. Neither Boushey's nor Hoffman's analysis included any controls for income or wages.

In addition, Hoffman added marriage–child interaction terms for specific years, in both ordinary least squares and logit formulations, to Boushey's regressions in order to differentiate the effect of children on married women and the effect of children on single women in each year. He found that in 1984 the negative effect of children on married women's labor force participation was 15.5 percentage points lower than it was on single women's labor force participation. He then found a decreasingly negative effect of children on single women's participation from

1984 through 2004, to the point that children had virtually no effect on their participation by 2004.

However, Hoffman calculated that, although the effect of children on married women actually turned from negative to positive between 1984 and 1993 in the ordinary least squares formulation, it turned negative again between 1993 and 2000 and then remained around the same level through 2004. The logit estimates follow the same pattern and show, from 1984 to 2004, a net change in the effect of at least one child on the probability of a married woman being in the labor force of over 15 percentage points (from -25.6 percent to 41.2 percent, with all other variables held constant). As Hoffman points out, these results are similar to those found by Cohaney and Sok²⁸ for mothers with infants.

Although Hoffman's aforementioned results describe the effect of all children under age 18, Hoffman also considered separately the effect of children 0–5 and that of children 0–2. He found that the results for 2000 and 2004 were even more pronounced for this group, with married mothers with children 0–2 years of age 12.2 percentage points less likely to be in the labor force than their counterparts were in 1989. However, as mentioned earlier, Hoffman's analysis excluded controls for income and wages.

The question that arises, then, is what has happened since 2004? There are now CPS data that go through 2009, and by Hoffman's methods, these data suggest that, beginning around 2004, women's labor force participation rates leveled off or even increased slightly. Hoffman's results indicated that more change occurred from 1993 to 2000 than from 2000 to 2004. Were the effects measured in these studies simply one-time occurrences, or have they persisted? And did these analyses provide spurious results because of the lack of controls for income and wages?

Trends in women's participation rates

Given the varied pictures of women's labor force participation presented in the literature to date, it is worth examining trends in their participation by marital status, education level, and presence of children. To do this, this article presents detailed breakdowns of March data from the CPS for women aged 25–54 in the years 1977–2009.

Chart 1 displays labor force participation rates by marital status,²⁹ level of education, and presence of children for women aged 25–54. The graphs on the left side present the data for married women, who have been the focus of virtually all of the recent literature. There one can see declines in the participation of women with children begin-

ning as early as the mid-1990s, and one can see that the declines are the most pronounced for women with more than 16 years of education. These declines appear to be the ones that triggered the various articles in the popular press about professional women moving to the "Mommy track." For married women with at least 16 years of education who have children, the trend continued past the year 2000 but then reversed; however, for those with less than 16 years of education and with children under age 6,³⁰ the decline has proceeded nearly unabated. There has even been some decline beginning in the early 1990s among married women with 16 years of education and no children under age 18.

That decline in the labor force participation rate among women with no children under 18 has been even more pronounced for single women, a phenomenon that is visible in the panels on the right side of chart 1. Since the late 1980s, single women with no children and less than 16 years of education have experienced a decline of 7.2 percentage points, those with 16 years of education have experienced a decline of 6.2 percentage points, and those with more than 16 years of education have experienced a decline of 3.6 percentage points. For single women with children under 6, those with 16 years of education or more also have shown a decline in participation, but there has been a rebound among those with more than 16 years of education that began around 2002. Women with children and with less than 16 years of education exhibited marked increases in participation that began around the mid-1990s and may have been strengthened by welfare reform, but their rates have declined by about 3.5 percentage points since the turn of the century. On the whole, the picture has been one of decline in labor force participation for all single women, a decline that, for a number of groups of single women, began as early as the late 1980s or early 1990s.

Although the patterns in chart 1 are notable, there are also many substantive trends that underlie those patterns. Charts 2 and 3 examine some of these trends more closely, looking at single and married women by education level and age group. Chart 2 examines women with children under age 6, whereas chart 3 looks at women without any children under 18.

Some of the most substantial movements in chart 2 in the past 10 or 15 years have been among women aged 25–29 with children under 6. Within this demographic, the labor force participation rate has declined for single women with at least 16 years of education (by over 9 percentage points), married women with at least 16 years of education (by nearly 7 percentage points), married

Chart 1. Labor force participation rates of women age 25–54, by marital status, level of education, and presence of children, annual data, 1977–2009

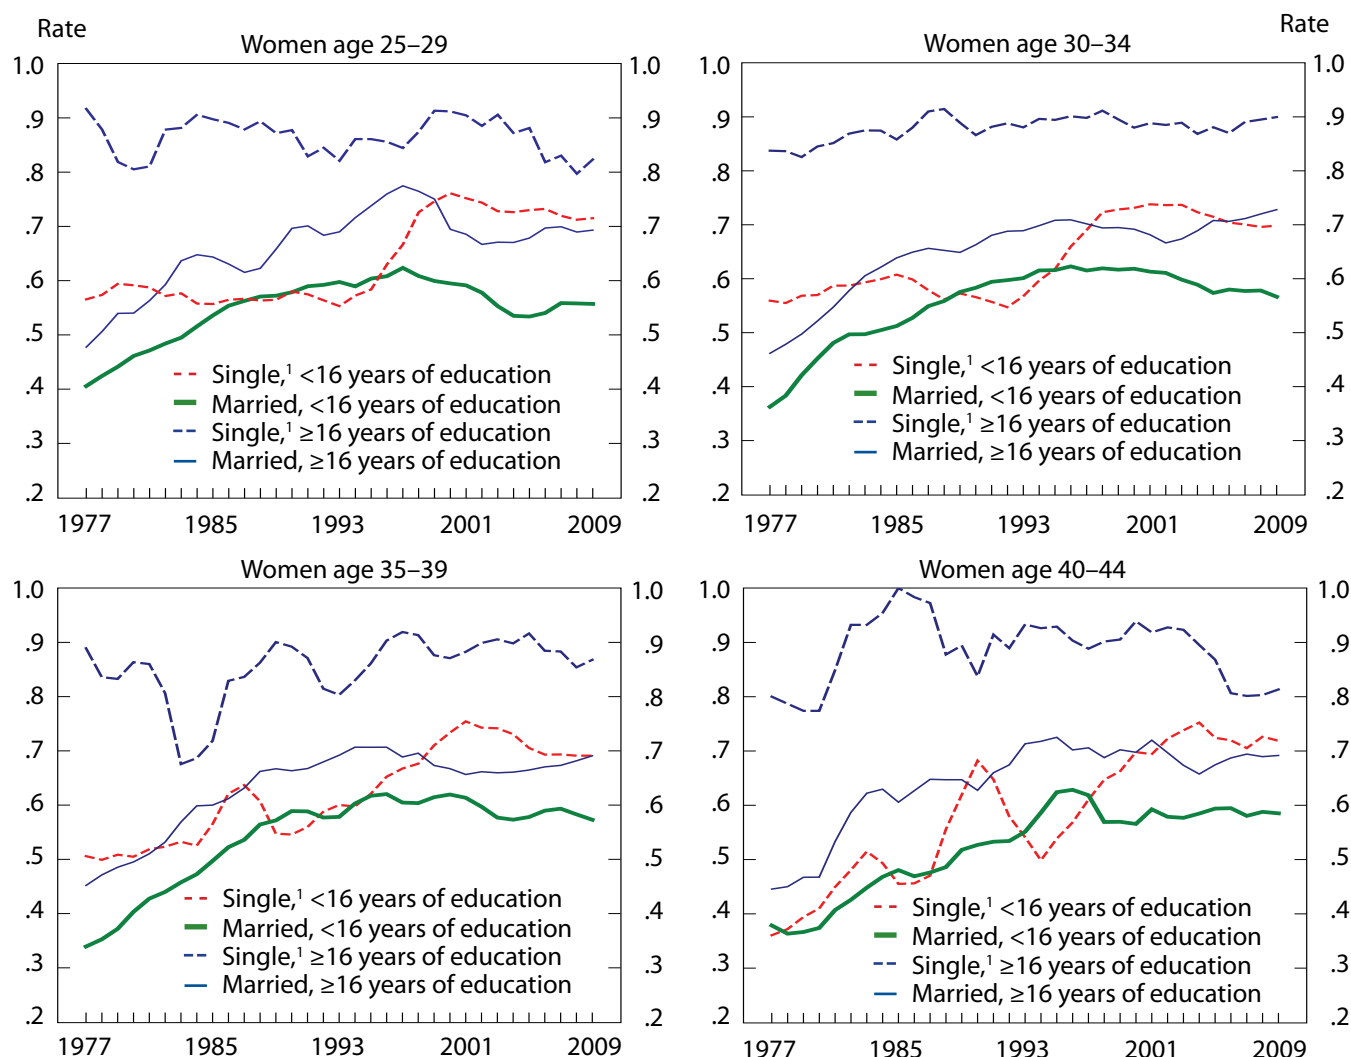

¹ Comprises divorced, widowed, and never-married women, as well as those with spouse absent.

² All women who have both a child under age 6 and a child age 6–17 are placed in the "under age 6" category.

NOTE: There are some data in the chart that are not statistically significant.

Chart 2. Labor force participation rates of women age 25–54 with at least one child under age 6, by age, marital status, and level of education, annual data, 1977–2009

¹ Comprises divorced, widowed, and never-married women, as well as those with spouse absent.

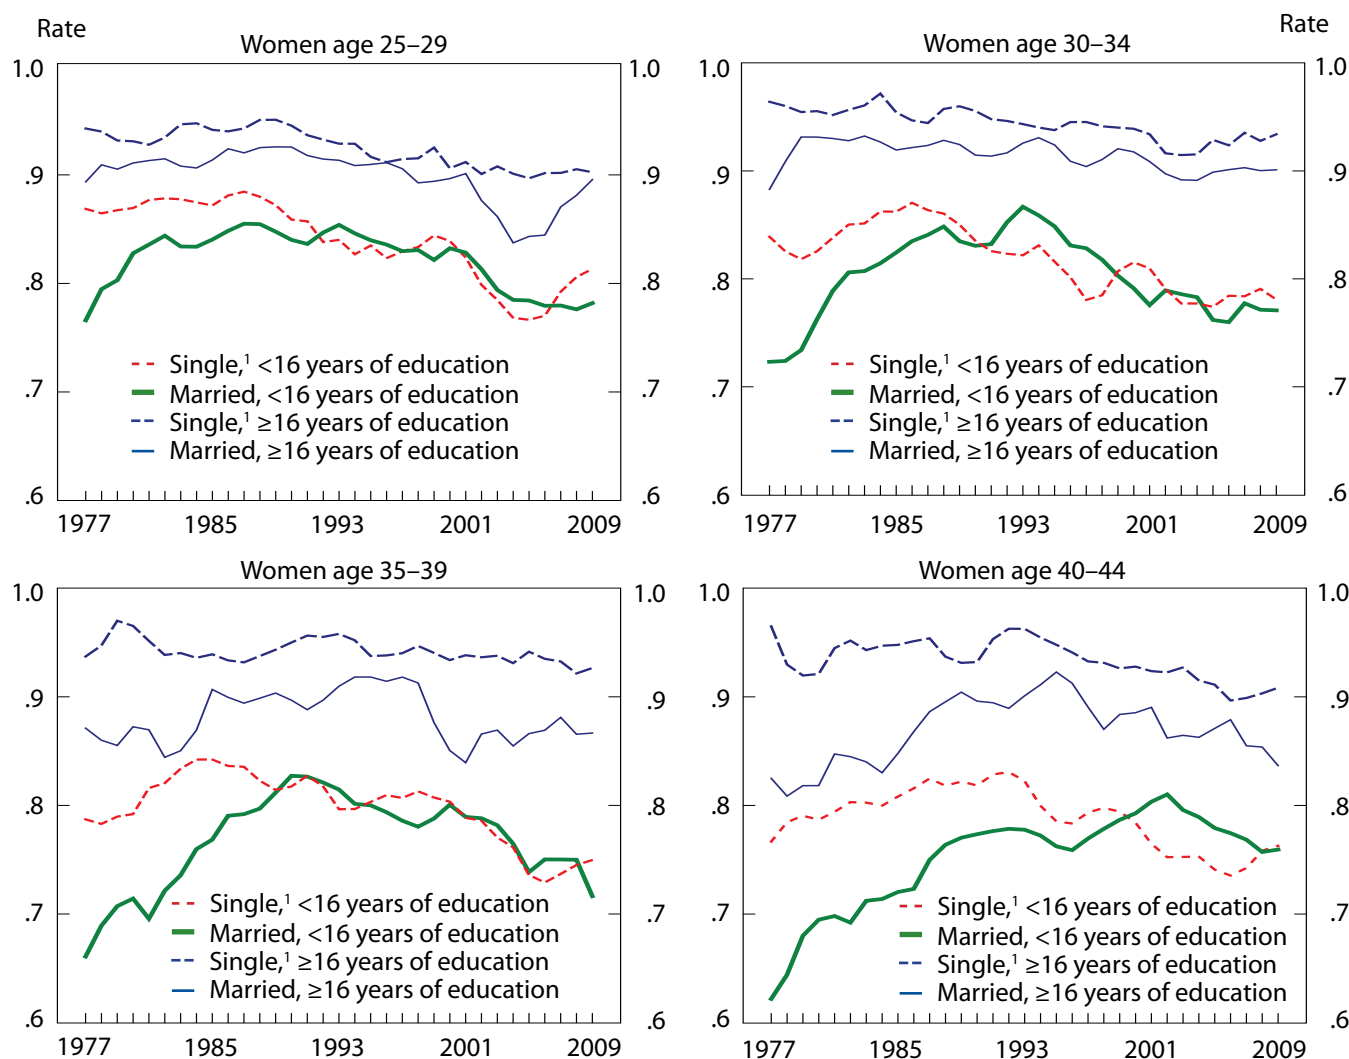

NOTE: There are some data in the chart that are not statistically significant.

women with less than 16 years of education (by over 8 percentage points), and single women with less than 16 years of schooling (by nearly 3 percentage points). In addition, the rate declined among single women aged 40–44 with at least 16 years of education (by over 12 percentage points). The rates for women aged 30–34 with less than 16 years of education and children under 6 also have declined marginally. The trend among single college graduates aged 40–44 that appears in chart 2 corresponds with that in the many recent articles about older women with young children withdrawing from the labor force, although those articles tended to focus almost exclusively on mar-

ried women. And those articles appear not to have shown the trend of decline during the past several years among 25- to 29-year-olds with children younger than 6: this is a notable trend that may signal a shift in behavior for this cohort.

Perhaps the most surprising results are presented in chart 3, however, which looks at women without any children under 18. Here we see declines—most extending back to the early 1990s or even late 1980s—among all groups based on education, marital status, and age, except for college graduates aged 35–39. The trends in these graphs seem to contradict the hypothesis that children are

Chart 3. Labor force participation rates of women with no children under age 18, by age, marital status, and level of education, annual data, 1977–2009

¹ Comprises divorced, widowed, and never-married women, as well as those with spouse absent.

NOTE: There are some data in the chart that are not statistically significant.

the reason for women's withdrawal from the labor force.

Accompanying these marked changes in labor force participation was a notable increase in the number of children from the 1999–2001 period to the 2007–09 period for almost every group. The figures for mean number of children can be seen in tables A-2 and A-3 of the appendix, which show an increase of 7.7 percent in the number of children under age 6 for married women and an increase of 15.5 percent in the same measure among single women. In some subgroups, the increase was much more marked. This was particularly so among women with more than 16 years of education: married women's

number of children under 6 increased by 24.9 percent between 1999–2001 and 2007–09, and single women's number of children aged 6–17 increased by 29.6 percent in the same period. For single women with 16 years of education, the number of children under 6 increased by 27.9 percent from 1999–2001 to 2007–09.

Data and method

The objective of this study is to examine trends econometrically as an update to the Blau and Kahn study,³¹ which estimated the elasticity of hours worked with respect to

wages for married women and found a trend of decline between 1979–81 and 1999–2001. As mentioned earlier, Blau and Kahn found evidence of a sharp rightward shift of the labor supply function for married women during the 1980s. They modeled annual hours worked in three 3-year groupings—1979–81, 1989–91, and 1999–2001—by use of March data from the CPS for married women aged 25–54 with spouse present, including wage data from the women’s spouses.

The analysis presented in this article draws on March CPS data for all women aged 25–54, and for the husbands of those married with spouse present. The Blau and Kahn 3-year groupings were used, and data from the 2007–09 period were added to provide a more up-to-date 3-year grouping. In addition, this analysis includes the 1984–86 period in order to better examine trends from the 1980s, when female labor force participation was increasing at the fastest rate, before the declines seen in charts 1–3.

The analyses presented here examine not just married women with spouse present, but also single women—a group that has been defined in this article as comprising divorced, widowed, and never-married women, as well as those with spouse absent. Single women are included because of the notable trends observed for them in charts 1–3. Both groups—single women and married women, including husbands—exclude those in the military, the retired, and those with allocated³² hours or weeks worked. March-supplement weights were used throughout the analysis, with the weights divided by the sum of weights in each year in order to ensure that each year in a 3-year grouping received equal weight. Summary statistics for the data used are presented in the appendix of this article.

The model estimated was

$$H = \beta_0 + \beta_1 \ln W_w + \beta_2 \ln W_h + \beta_3 I + B'X + u,$$

where H is annual hours worked (including those with zeroes); W_w is the woman’s own (instrumented) wage; W_h is the husband’s (instrumented) wage, which is excluded from the equation for single women; I is nonwage income, which comprises interest, dividends, and rent; and X is a vector of control variables. The control variables include age, age squared, four education dummies, three race dummies—for the wife and the husband in the married women’s equation, and for the woman only in the single women’s equation—number of children under age 6, number of children aged 6–17, two year dummies, eight region dummies, and two indicators of Metropolitan Statistical Area (MSA) status.

The method employed in this article comprised three steps. In the first, hourly wages were calculated—in 2008 dollars by use of the Consumer Price Index—as total annual wage and salary income divided by annual hours worked, with the latter calculated as the number of weeks worked times the usual number of hours worked per week in the previous year. The annual wage and salary income was multiplied by a factor of 1.45 if topcoded, as it was in Blau and Kahn’s study. The hourly wage was imputed for those with no reported wage, the self-employed, and those whose calculated wage fell outside the range of \$2.50–\$250 in 2008 dollars (again following Blau and Kahn). The imputation process was based on separate regressions of the natural logarithm of the wage (henceforth, “log-wage”) for those with less than 20 weeks worked and those with 20 or more weeks worked, separately for men, married women, and single women. That is, it was assumed, as in Blau and Kahn, that wages should be imputed on the basis of the reported wages of groups of people with similar numbers of weeks worked. As was the case in the Blau and Kahn study, the regressions included age and age squared, two year dummies, four education dummies, three race dummies, eight region dummies, and indicators for “central city” and “other MSA.”

In the second step, with the women’s and their spouses’ wages treated as endogenous, wages were instrumented by regressing logwage on age and age squared, four education dummies, three race dummies, eight region dummies and the two indicators for MSA status. In addition, following on Blau and Kahn, a series of dummy variables representing wage deciles was included, which served as excluded instruments in the final hours equations. As indicated in Blau and Kahn, use of the deciles “corrects to some degree for measurement error in the wage” (p. 406).

The third step involved calculating estimates with the aforementioned equation, the results of which are presented in table 1. This equation was treated as a weighted instrumental variables linear model. However, two alternative methods were tested, for sensitivity. In the first, as in Blau and Kahn, a median regression was estimated in order to take account of the fact that, with higher levels of labor force participation, many women might be constrained to a standard work week. A regression at the median removes this constraint. The results of that median regression for married women are presented in table 2. The second alternative method was based on that of Heim,³³ who used the Heckman method, estimating an inverse Mills ratio to be included in a logwage regression, to produce an estimated logwage to be included along with the inverse Mills ratio in a regression for hours

Table 1. Instrumental variables estimates for women age 25–54, by marital status, selected years, 1979–2009 (dependent variable is annual hours worked, with zeroes included)

Measure	1979–81	1984–86	1989–91	1999–2001	2007–09
Married women					
Natural log of own wage.....	509.4 (10.62)	638.7 (10.14)	645.0 (10.14)	346.3 (11.76)	395.6 (10.55)
Natural log of husband's wage.....	–285.9 (9.67)	–272.5 (9.39)	–259.7 (9.88)	–179.3 (11.92)	–208.0 (10.72)
Nonwage income (in thousands) ¹	–2.66 (0.42)	–2.60 (0.37)	–1.84 (0.40)	² –0.81 (0.41)	² –0.84 (0.44)
Number of children younger than 6 years	–380.2 (5.6)	–350.0 (5.93)	–349.6 (6.09)	–320.0 (8.75)	–288.4 (7.64)

¹ Nonwage income comprises interest, dividends, and rent.

² Significant at the .05 level.

³ Comprises divorced, widowed, and never-married women, as well as those with spouse absent.

⁴ Not significant even at the .10 level.

NOTE: Standard errors are in parentheses. All coefficients are statistically significant at the .01 level or higher except for those indicated otherwise. All regressions include age, age squared, four education dummies, and three race dummies for women and for the husbands of married women, as well as two year dummies, eight region dummies, and indicators for central city, other MSA, and non-MSA.

worked.³⁴ The results of that procedure—which are very similar to those presented in table 1—are available from the author on request.

Results

The results in table 1 are similar to those in Blau and Kahn in regard to the decline in the elasticity of women's hours worked with respect to their wages (henceforth, "own-wage elasticity"). The table shows a very slight decline in this elasticity from the 1979–81 period (.531) to the 1989–91 period (.522), and then a stronger decline from the 1989–91 period to the 1999–2001 period (.253).

However, the magnitudes of the elasticities are less than those of the elasticities estimated by Blau and Kahn (.766, .584, and .357, respectively).

However, as suggested in an article by Chinhui Juhn and Kevin M. Murphy,³⁵ the own-wage elasticity estimated here actually increased during the first half of the 1980s, from .531 in the 1979–81 period to .591 in the 1984–86 period, before declining to .522 in 1989–91. More notable in table 1, however, is the fact that the own-wage elasticity appears to have risen again between the 1999–2001 period and the 2007–09 period (from .253 to .292). A similar pattern is demonstrated in the bottom half of table 1, for single women, for whom the own-wage elasticity

first increases between 1979–81 and 1984–86, then declines to .115 in 1999–2001, and then rises to .202 in the 2007–09 period.

Similarly, the absolute value of the elasticity of married women's hours worked with respect to their husbands' wages (henceforth, "cross-wage elasticity"), presented in table 1, declined from 1979–81 to 1999–2001 (the actual value changed from $-.298$ to $-.131$), as in Blau and Kahn, but it, too, increased between 1999–2001 and 2007–09. (The actual value changed from $-.131$ to $-.154$.)

Most of the general patterns visible in table 1 also appear in table 2, which is based on median regressions. There, the own-wage elasticity rises from .736 in 1979–81 to .760 in 1984–86 and then declines to .271 in the 1999–2001 period, but rises again to .281 in 2007–09. And, as in table 1, the cross-wage elasticity falls from 1979–81 through 1999–2001 but then rises between 1999–2001 and 2007–09.

In order to explore these patterns further, separate regressions were run for various subgroups of married and single women, and the resulting elasticities are presented in table 3. Except for single women with 16 or more years of education, there exists the same pattern of increase in own-wage elasticity between 1979–81 and 1984–86 followed by a decline between 1989–91 and 1999–2001 in all groups. And except for married women with less than

16 years of education, and single women under age 35, there exists the increase in own-wage elasticity between 1999–2001 and 2007–09 that was demonstrated in tables 1 and 2. For single women with more than 16 years of education, the own-wage elasticity actually turned negative during the 1990s—probably a result of the dot-com boom during the late 1990s, which appears to have caused many women to make enough money that higher wages actually resulted in fewer hours worked. This hypothesis is consistent with Goldin's expectation that, as women become more career-oriented, their own-wage elasticity will approach that of men.³⁶

As regards cross-wage elasticity, the pattern in table 3 echoes that in tables 1 and 2 for all groups, except women with children under 6, for whom the elasticity failed to increase between 1999–2001 and 2007–09. But in general, the pattern has been one of decline in the cross-wage elasticity from 1979–81 through 1999–2001 with a rebound thereafter.

Tables 4 and 5 present estimates of elasticity of women's hours worked with respect to the number of children in two age groups: under 6, and 6–17. For nearly all groups of women in the tables, a decline in elasticity throughout the 1979–2009 period can be seen: children were having less and less influence on their mothers' hours worked during the timespan. For married women with 16 or more

¹ Comprises divorced, widowed, and never-married women, as well as those with spouse absent.

² Not statistically significant at the .01 level.

NOTE: The coefficients used to calculate elasticity all were significant at the .01 level or higher except for those indicated otherwise. Regressions included the following, where appropriate: age, age squared, four education dummies, and three race dummies for women and their husbands, as well as two year dummies, eight region dummies, and indicators for central city and other MSA. In all cases, elasticity was calculated by use of weighted means, based on March-supplement weights.

years of education and for married women with children younger than age 6, there was a very small increase from 1999–2001 to 2007–09 in the elasticity of hours worked with respect to the number of children younger than 6. Similarly, there was a very small increase between 1999–2001 and 2007–09 in the elasticity of hours worked with respect to the number of children younger than 6 for single women with 16 or more years of education and single women under 35.

Interpretation of results

In order to try to determine what factors lie behind the marked changes in labor force participation seen in charts 1–3, and the changes in elasticity seen in tables 3–5, it is helpful to look at estimated values of labor supply based on the equations underlying tables 3–5. These estimated

values can be broken down into components, and total estimated values can be compared with actual observed changes in labor supply. The results of such a procedure are presented in tables 6 and 7.³⁷ Table 6 breaks down estimates for the 1980s, when labor supply increased most dramatically in all groups, and table 7 does the same for the 2000–09 period, when so many reversals appear to have occurred.

Each table looks at married and single women separately. Lines 12 and 22 of table 6 indicate that, during the 1980s, significant increases occurred in all groups but that by far the most dramatic increases occurred for married women: the average increase for all married women was 276.42 hours, while for single women the comparable figure was 118.20 hours. For both married and single women, the largest increases occurred among those with exactly 16 years of education and those 35 years of age or older. But

close behind were married women with children under 6, the group that has been most often noted in the literature for a sharp increase in labor force participation in the 1980s.

For married women, the strongest force behind the increase in hours worked appears to have been their own

wage (see line 1): the part of the increase attributable to that wage was 59.77 hours. The next-strongest force was increases in educational levels, which contributed 19.49 hours (line 6). Husbands' wages contributed as well, since husbands' average wage declined during this period, leading women to supply more hours. For single women, the

largest contribution to increased hours was made by rising levels of education, which brought about an estimated increase of 36.42 hours (line 18). For both married and single women, the children they had made a positive contribution to hours worked (lines 8 and 19), since fertility declined overall during this period.

However, overall, the estimated increases fall far short of the actual observed increases in hours worked (lines 13 and 23). This same phenomenon was observed by Blau and Kahn for this period: they found that measured factors ac-

counted for at most 38 percent of observed increases, suggesting a marked shift to the right of the labor supply function during this period. In this analysis, the result is similar, with measured factors accounting for only 38.7 percent of the increase for married women, although the performance is better for single women, with measured factors accounting for 65.2 percent of the observed change. Thus, the shift appears to have been strongest among married women, probably because of the gradual acceptance of labor force participation among women with young children.

¹ Nonwage income comprises interest, dividends, and rent.

² Coefficient used to calculate the estimated effect was not statistically significant even at the .10 level.

³ Comprises divorced, widowed, and never-married women, as well as

those with spouse absent.

NOTE: All coefficients are statistically significant at .10 level or higher except for those indicated otherwise.

The poorest performance in explaining increases in hours worked—indicating the greatest shift in the labor supply curve—was for women under 35, a demographic in which measured factors accounted for only 22.5 percent of observed changes for married women and 14.4 percent for single women. The best performance was for women 35 or older: 49.7 percent for married women, and 79.2 percent for single women.

Table 7 displays the results of a similar analysis for the 2000–09 period, an analysis based on the equation used

for table 1. Whereas the unexplained portions of the increase in hours were positive in table 6 for all the groups of women in the table (lines 14 and 24)—indicating a rightward shift of the labor supply function—with one exception they are all negative in table 7 (again, lines 14 and 24). This, together with the estimated turnaround in elasticities for the 2000–09 period, suggests that the labor supply curve may have shifted back to the left during this period. This appears to be the case especially for single women, for whom the observed decline in hours worked

was the greatest (line 22). The overall change in hours for single women was a drop of 101.48, as compared with a decline of 13.46 hours for married women. The measured factors add up to a rise of 6.44 hours for single women, instead of the observed large decline.

The one exception to the apparent leftward shift in the labor supply curve in table 7 is married women with more than 16 years of education: for them, measured factors estimate an even larger decline in hours worked than what actually occurred. They also had the largest decline attributable to the number of children: 30.32 hours lost (line 8), which is very close to the observed overall drop of 28.66 in hours supplied (line 12). This is the only case in table 7 in which children might be thought responsible for women's reduction in hours worked in the labor market. For all other groups, the contribution made by children—despite the substantial rise in fertility—was fairly small (lines 8 and 19). As did married women with more than 16 years of education, single highly educated women, as noted earlier, exhibited a negative own-wage elasticity in the 1999–2001 period, and essentially bought back time for activities outside work because of their high wages.

In the 1999–2009 period, movements in women's own wages affected the number of hours spent at work much less than they did from 1979 to 1991 (lines 1 and 15). In fact, for single women in nearly every group, despite positive own-wage elasticities, wages had a negative effect on the number of hours worked (line 15). This is due to the fact that these women's imputed, instrumented average wages decreased during this period, as shown in the following tabulation:

Percent change in real imputed and instrumented wages for single women, 1999–2009

All single women.....	-1.0
With more than 16 years of education.....	-1.8
With 16 years of education.....	-1.1
With less than 16 years of education.....	-2.6
35 years old or older.....	-1.1
With no children younger than 18.....	-1.6
With children younger than 6.....	-1.1

For single women without children under 18, part of this decrease in the average estimated wage was probably due to a decrease in the proportion of these women accounted for by those with more than 16 years of education: their share fell by 13 percent during the 1999–2009 period, (although this was nearly matched by a decrease of 11 percent in the share accounted for by those with less than 12 years of education during the same period). This

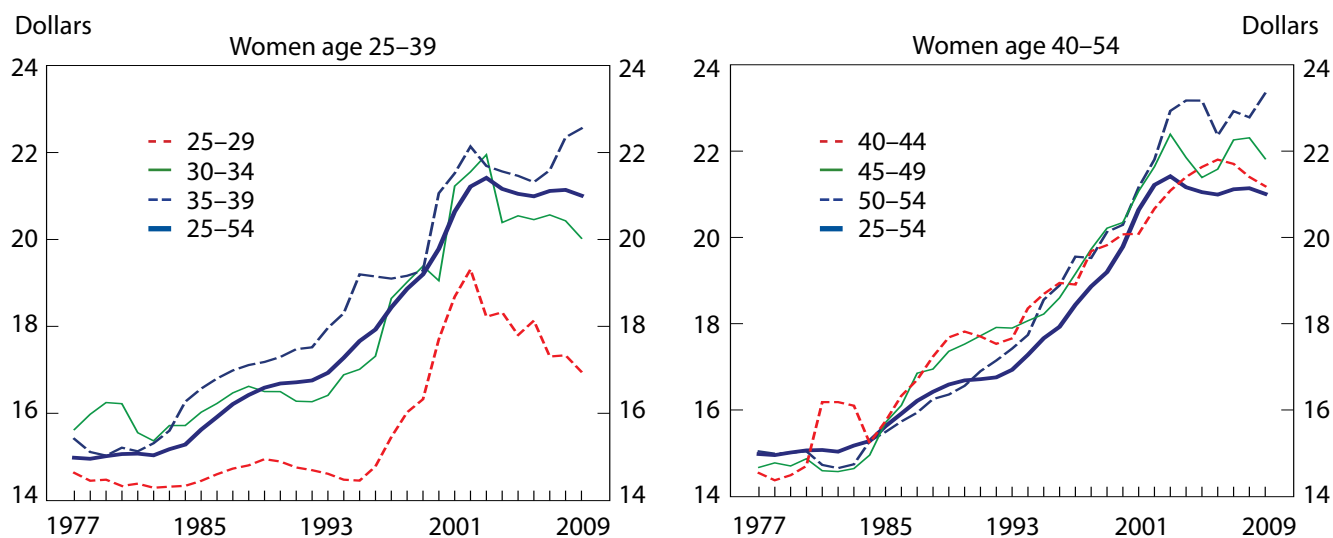

decline in the share of single women without children under 18 accounted for by those with more than 16 years of education was not due to a decline in the overall share of more highly educated women: the share of women with more than 16 years of education among all married women aged 25–54 rose by 41 percent, while the corresponding share for single women rose by 12 percent (calculated with data from tables A-2 and A-3 of the appendix). Similarly, the share of highly educated women among single women with children rose by 29 percent. Thus, the women with the highest levels of education were marrying and having children in fairly high proportions during the 1999–2009 period. This is another feature of the period that attracted so many articles in the popular press.

The movement in the instrumented wages of single women follows the overall pattern that occurred during this period, shown in chart 4. The chart presents observed wages of women reporting positive hours worked and positive earnings in the period from 1977 to 2009 (for earnings in 1976–2008), as opposed to the imputed and instrumented wages used in the regressions. Chart 4 shows a period of substantial increase in women's average wages, in nearly all age groups, between 1980 and the early 2000s. For women 25–29 years old, this increase did not begin until the mid-1990s, which explains the smaller effect that these younger women's wages had on the hours they worked in the labor market during the 1980s. However, after the early 2000s women's wages decreased across the board, for all age groups. This was especially the case for women aged 25–29—which may be a reason, when taken together with the increased responsiveness of 25- to 29-year-old women to their own wage, for the significant reduction in the labor force participation of these women, shown in chart 3.

Women who leave the labor force

How do women who drop out of the labor force differ from those who remain—and have the characteristics of those who leave the labor force changed in recent years? Table 8 considers these questions, examining the two groups that have, overall, dropped out in the greatest numbers: single women, and women without any children younger than 18. The table presents, by level of education, some of the characteristics of women who were not in the labor force during the year in question but had been the previous year relative to the characteristics of women who remained in the labor force. Thus, for example, in the upper left corner, it can be seen that, in the periods before 1999 that were studied (1979–81, 1984–86, and 1989–91), single women with less than 16 years of education who dropped out of

Chart 4. Mean observed hourly wages¹ of women aged 25–54, in 2008 dollars, annual data, 1977–2009

¹ "Observed wages" refer to the wages of women who worked a positive number of hours and for whom wages are reported, as opposed to wages that were imputed or instrumented.

the labor force had worked only 49 percent as many hours during the year in which they were in the labor force as those who did not drop out worked during the same year. The pattern of women who left the labor force having worked fewer hours when they were in it than women who did not leave the labor force is common across years and levels of education, for both single women and childless women. However, it is also the case that, compared with before 1999, from 1999 onward the dropouts had worked slightly more relative to those who remained.

Similarly, in the periods before 1999 that were studied, single women and childless women who dropped out had, on average, earned less than 85 percent of the hourly wage of those who remained—but this percentage rose in all cases from 1999 on. In the 1999–2001 period, in all but one case they had earned *more* than those who had not dropped out. However before 1999, those who dropped out of the labor force and had more than 16 years of education had enjoyed more than 70 percent more nonwage income (interest, dividends, and rent) than those who remained—but in all cases this advantage dropped significantly after 1999.

And finally, except for those with more than 16 years of education, single women who dropped out had, on average, more children than those who did not drop out. But here again there was a shift beginning with the 1999–2001 period: the ratio of the number of children per single woman who dropped out of the labor force to the num-

ber of children per single woman who stayed in the labor force had dropped. The only instance in which the ratio rose was for single women with more than 16 years of education in the 1999–2001 period: those who had dropped out had 23 percent *more* children in that period than their counterparts who had not dropped out, after having had 8 percent *fewer* before 1999. This again is consistent with the "opting out" stories reported in the popular press.

Thus, as reflected in the shifts in elasticity reported in earlier tables, there were significant shifts in the characteristics of women who dropped out in 1999 or later: they on average had worked more hours, earned more per hour, enjoyed less nonwage income, and had fewer children.

MUCH OF THE RECEIVED WISDOM regarding women's labor force participation has been turned on its head in the last decade or so. Already widely noted has been the decline in labor force participation among highly educated married women with children under age 6, which appears to have begun in the mid-1990s. But what seems to have passed under the radar has been the significant change that has occurred among women without children under 18, especially those who are single. For women without children younger than 18, declines have been occurring since the early 1990s or even the late 1980s. Also notable have been the declines that have occurred in the 25–29 age group, for whom labor force participation

Table 8. Ratio of various characteristics of women who left the labor force¹ to the same characteristics of those who remained,² selected years, 1979–2009

Time period	Hours worked	Hourly wage	Nonwage income ³	Number of children under age 6	Number of children age 6–17

Average of 1979–81, 1984–84, and 1989–9150	.84	1.70
1999–200155	1.09	1.26
2007–0956	1.09	.76

¹ A woman is defined as having left the labor force if she worked positive hours in year $t-1$ and was not in the labor force in year t .

² For example, on average for the years 1979–81, 1984–86, and 1989–91, the ratio of the average number of hours worked in year $t-1$ by single women who left the labor force to the average number of hours worked

during the same year by single women who remained in the labor force was 0.49 (the statistic in the upper-left corner of the table).

³ Nonwage income comprises interest, dividends, and rent.

⁴ Comprises divorced, widowed, and never-married women, as well as those with spouse absent.

is lower today than it was in the late 1990s or even, in some cases, the late 1980s. In addition, women with more than 16 years of education have been marrying in large numbers, and both single and married women among the highly educated have been having children, with numbers of children increasing by more than 25 percent since 1999–2001. In some cases these trends have abated somewhat since about 2005, but for nearly all groups of women without children under 18, and for women with children and less than 16 years of education, the declines have continued through 2007–09.

This article has attempted to analyze these trends and others econometrically, and has found a number of other trends. Own-wage elasticities, which had been declining since the 1980s, have increased since 1999–2001 for

both married and single women; cross-wage elasticities for married women, which had been declining in absolute value since 1979–81, have increased in absolute value since 1999–2001.

In addition, for nearly all groups of women, the negative elasticity of hours worked with respect to number of children has declined in absolute value continuously since 1979–81. The only exception to this rule has been married women with more than 16 years of education and married women with children under 6, for whom elasticity has increased marginally in absolute value since 1999–2001. Among single women, elasticity of hours worked with respect to the number of children under age 6 has declined continuously since 1979–81 for all groups except for that with exactly 16 years of education and that under

age 35. As regards elasticity with respect to the number of children aged 6–17, for single women with more than 16 years of education, the elasticity has increased very little in absolute value since 1999–2001.

Yet, for the most part, the observed changes in elasticity cannot explain the marked changes in the number of hours supplied to the labor market since 2000. The overall drop in mean annual hours supplied for single women was 101.48, but adding up measured factors results in an estimated rise of 6.44 hours. For married women, the actual drop was only 13.46 hours, but for them, summing measured factors results in an estimated rise of 8.79 hours. These differences suggest that, whereas the labor supply curve appeared to have shifted markedly to the right in the 1980s, and less markedly to the right in the 1990s, there was a leftward shift between 1999–2001 and 2007–09, which was most marked for single women.

The only exception to this trend was married women with more than 16 years of education, for whom measured

factors add up to an even larger drop in hours worked than what actually occurred. This was largely due to their response to the presence of children. This was the only group for whom the decline in women's labor force participation might be attributed to the presence of children.

Thus, this analysis, unfortunately, leaves largely unexplained the sometimes dramatic shifts that have occurred in the labor market behavior of women—especially single women—since the 1990s. Perhaps, like the attitudinal shift in the 1970s and 1980s that made it more socially acceptable for a mother with children to enter the labor force, there currently exists an attitudinal shift towards accepting women's ability to choose between home and labor market. Further analysis could involve an examination of the sources of income and the living arrangements of those single women and childless women who have been choosing to withdraw from the labor force since the turn of the century. □

²⁹ “Married” is defined here, as it is in Blau and Kahn's 2007 article, as married with spouse present. “Single” comprises women in any of the following categories: married with spouse absent, divorced, separated,

widowed, and never married.

³⁰ This refers to women who have at least one child younger than 6 years. There is also a category for women with at least one child age 6–17. Women who have both a child younger than age 6 and a child age 6–17 are classified only in the category for a child younger than age 6.

³¹ Blau and Kahn, “Changes in the Labor Supply Behavior.”

³² People with “allocated” time worked are those for whom time spent at work was imputed because there was no time reported.

³³ Heim, “The Incredible Shrinking Elasticities.”

³⁴ The Heim model for hours supplied (that is, hours worked) includes age, years of education, the unemployment rate (by State, age, and education group, calculated from the CPS), non-wage income (including husbands' earnings for married women), two year dummies, three race dummies, three region dummies, and two indicators of MSA status (as well as the inverse Mills ratio). The model for the natural log of the wage included the cubics of age and years of education, two year dummies, three race dummies, three region dummies, and two indicators of MSA status (and the inverse Mills ratio). The model for estimating the inverse Mills ratio included the cubics of age and education, two year dummies, the unemployment rate, the number of children under age 18 and an indicator of the presence of children under 6, three race dummies, metropolitan size, three region dummies, and two indicators of MSA status.

³⁷ Table 6 is based on the regression equation reported in table 1 for the period 1989–91. However, results based on the equations for other years produce very similar results. Similarly, although table 7 is based on the regression equation for 2007–09, similar results were obtained using equations from the other years. These other results are available on request.

Appendix A: Explanation of data

The data used in the analyses in this article were taken from the March Current Population Survey (CPS). (The microdata were compiled by Unicon Corporation.) For the graphs of labor force participation rates and average wages, the years 1977–2009 were used. These data are for all women aged 25–54 and were weighted by use of the March-supplement weights. Labor force participation was identified with the recoded responses to the question about employment status in the CPS. Annual wages were calculated as wage and salary income divided by the number of annual hours worked, which in turn was calculated as weeks worked in the year times usual hours worked per week.

For the econometric analyses, the years 1979–81, 1984–86, 1989–91, 1999–2001, and 2007–09 were used in order to attempt to reproduce and update results in Blau and Kahn's 2007 article,¹ with 1984–86 added in order to obtain more informa-

tion about changes that occurred in the 1980s. The data cover women aged 25–54 and include the wages of the men aged 25–54 married to the women in the sample.² “Single” women in the analyses include married women with spouse absent, and divorced, separated, widowed, and never-married women. Husbands and wives were matched by use of the hierarchical structure of the CPS data files.

As in the Blau and Kahn article, people with allocated³ hours or weeks worked were dropped from the data. In addition, people in the military have been excluded and, because Blau and Khan selected this age group in order “to abstract from issues of school and retirement for both husbands and wives,” those who were retired were excluded as well. An attempt was made to exclude people enrolled in school, but it was determined that the data on this group are not consistent over the years covered. The number of people in each category that were dropped from

the data is indicated in table A-1 of the appendix.

The March-supplement weights were used in all analyses in this article, and, in order to ensure that each year is given equal weight in every group of 3 years, the weights were divided by the sum of weights in each year to make them sum to 1 in each year. Because the method of reporting educational attainment was changed beginning in 1992, David Jaeger's correspondence method⁴ was used to determine the highest grade completed after that date.

All dollar figures are expressed in constant 2008 dollars. As in the Blau and Kahn article, topcoded wages were multiplied by a factor of 1.45. Income other than wage and salary income was calculated as the sum of income from interest, dividends, and rent. Following Blau and Kahn, wages were imputed for those who were self-employed, those who reported no income,

and those whose hourly wage was calculated as falling outside the range of \$2.50–\$250 in 2008 dollars. The imputation process was based on regressions of reported valid wages. For those reporting less than 20 weeks worked per year, imputed wages were based on a regression using those with a valid wage who worked less than 20 weeks. For those reporting 20 or more weeks worked, imputed wages were based on a regression using those with a valid wage who reported 20 or more weeks worked. This process was carried out separately for married women with spouse present, single women, and husbands with a spouse present. The regressors used were age, age squared, five education categories (less than 12 years, 12 years, 13–15 years, 16 years, and 17 years or more), four race categories (White, Black, Hispanic, and other), eight region dummies, and metropolitan area indicators (central city, other MSA, and non-MSA).

Notes

¹ Francine Blau and Lawrence M. Kahn, "Changes in the Labor Supply Behavior of Married Women: 1980–2000," *Journal of Labor Economics*, July 2007, pp. 393–438.

² If a woman was 25–54 years of age but her husband was not, neither the woman nor the husband were included in the sample.

³ People with "allocated" time worked are those for whom time spent at work was imputed because there was no time reported.

Fatal occupational injuries at road construction sites, 2003–07

Stephen Pegula

During the 5 years from 2003 to 2007, 639 workers were killed at road construction sites, according to data from the Bureau of Labor Statistics Census of Fatal Occupational Injuries (CFOI) program.¹ The majority of these fatal occupational injuries were incurred by workers in the highway, street, and bridge construction industry.²

This report is an update of an earlier analysis of fatal occupational injuries at road construction sites from 1995–2002 that was published in the December 2004 issue of the *Monthly Labor Review*.³ While total fatal occupational injuries declined nearly 10 percent from 1995 to 2007, fatal occupational injuries at road construction sites have increased in number and as a percentage of all fatal occupational injuries. (See table 1.)

There are many ways to define a road construction site. The CFOI program defines road construction sites as including construction, maintenance, or utility work on a road, highway, or street. The 2009 edition of the *Manual on Uniform Traffic Control Devices* from the Federal Highway Administration defines work zones as follows:

A work zone is an area of a highway with construction, maintenance, or utility work activities.

Table 1. Fatal occupational injuries at road construction sites by year and percentage of all fatal occupational injuries, 1995–2007

Year	Fatalities	Percentage of all fatalities
1995	94	1.5
1996	93	1.5
1997	94	1.5
1998	113	1.9
1999	124	2.0
2000	106	1.8
2001	118	2.0
2002	102	1.8
2003	110	2.0
2004	119	2.1
2005	165	2.9
2006	139	2.4
2007	106	1.9

A work zone is typically marked by signs, channelizing devices, barriers, pavement markings, and/or work vehicles. It extends from the first warning sign or high-intensity rotating, flashing, oscillating, or strobe lights on a vehicle to the END ROAD WORK sign or the last TTC [temporary traffic control] device.⁴

The manual also details several elements commonly found at road construction sites, including proper signage, channeling devices such as cones and barricades, buffer spaces and lane tapering to protect workers, and flagger control. It also provides diagrams and procedures for sample work zones based on the type of lane closures required.

This report focuses on the events that resulted in the fatal work injuries at road construction sites as defined by the CFOI program over the 2003–07 period.

Overall

From 2003 to 2007, there were 639 fatal occupational injuries that occurred at road construction sites, which accounted for 2 percent of fatal occupational injuries overall. During these 5 years, the high was in 2005 (165 fatalities) and the low was in 2007 (106 fatalities).

Male workers accounted for over 97 percent of the fatal work injuries at road construction sites, compared with 93 percent for all fatal work injuries and 99 percent for fatal work injuries in the construction industry.⁵ Hispanic or Latino workers were slightly more likely to be killed at a road construction site than they were in all fatal workplace injuries.

Just under 17 percent of the workers killed at road construction sites from 2003 to 2007 were born outside of the United States. Almost 80 percent of these foreign-born workers were Hispanic or Latino. Approximately 2 out of every 3 foreign-born workers killed at a road construction site were born in Mexico. Texas had the largest number (31) of fatal occupational injuries incurred by foreign-born workers at road construction sites.

Focus on fatal events

The most common event⁶ associated with fatal occupational injuries incurred at a road construction site was *worker struck by vehicle, mobile equipment*. Of the 639 total fatal occupational injuries at road construction sites during the 2003–07 period, 305 were due to a worker being struck by a vehicle or mobile equipment. (See table 2.)

More workers were killed by construction-related vehicles or equip-

Stephen Pegula is an economist in the Office of Safety, Health, and Working Conditions, Bureau of Labor Statistics. Email: Pegula_S@bls.gov.

Table 2. Fatal occupational injuries at road construction sites due to workers being struck by vehicles or mobile equipment by type of vehicle or mobile equipment, 2003–07

ment⁷ (38 percent) than by cars, tractor-trailer trucks, and vans (33 percent). This finding was consistent with the 1995–2002 data.

A total of 100 fatally injured workers (33 percent) were employed as construction laborers. Another 37 (12 percent) were employed as highway maintenance workers. First-line construction supervisors and managers accounted for 28 (9 percent) of the fatalities, while crossing guards (including flaggers) accounted for 27 fatalities (9 percent). Some other important characteristics involving this type of fatal work injury are as follows:

- Workers were fatally struck 101 times by a vehicle or mobile equipment that was backing up. In 60 of these cases, the worker was fatally struck by a dump truck that was backing up.
- In the cases in which the worker was struck by a vehicle backing up, there were 25 cases in which the back-up alarm was referenced in the case narrative. In 11 of these cases, the back-up alarm of the vehicle

or mobile equipment was not functioning or did not exist. In 14 of these cases, the back-up alarm of the vehicle or mobile equipment was functioning but did not alert the decedent.

- Sixty one workers were killed while directing or flagging traffic.
- Ten workers were killed by drunk drivers.

The next most common event leading to a workplace fatality at a road construction site was a *highway or nonhighway incident*.⁸ A total of 153 workers were killed at road construction sites in highway or non-highway incidents. Of these, 87 (57 percent) were due to a collision. In 42 of these collision cases, the decedent was driving a tractor trailer. In 47 of the cases, the decedent's vehicle struck a tractor trailer. (There were 25 cases in which the decedent's tractor trailer struck another tractor trailer.)

Forty fatal workplace injuries resulted from an overturned vehicle or mobile equipment; the decedent was driving a steam roller or road paver in 15 of these cases. There were 21 cases of a victim falling from a vehicle; the decedent was then struck by the vehicle in 15 of the cases.

Over the 2003–07 period, workers at road construction sites were fatally *struck by a falling object* 34 times. In 8 cases, the object fell from a crane (or the crane itself was the falling object), while 4 cases involved the object falling from a backhoe.

A total of 31 workers died as a result of fatal *falls* at road construction sites. Of these, 24 occurred at bridge/overpass construction sites. In the 23 instances in which the height was known for the fall at a bridge/overpass construction site, the median height of the fall was 50 feet.

Twenty three workers were killed as a result of *contact with electric current* at a road construction site. In total, 21 of these cases involved contact with overhead power lines. In 15 of these cases, a machine or item contacted the power lines and electrocuted the decedent rather than the decedent contacting the power lines directly.

Location and time

Approximately 11 percent of fatal workplace injuries at road construction sites occurred in Texas. Florida, California, Georgia, and Pennsylvania also have a sizable number of fatal occupational injuries that occur at road construction sites. (See table 3.)

In terms of time and date, fatalities at road construction sites tend to be more clustered around the traditional work time and workdays than workplace fatalities in general. For example, approximately 70 percent of road construction site fatalities during the 2003–07 period occurred between the hours of 8:00 a.m. and 4:59 p.m. (See table 4.) The corresponding figure for all workplace fatalities during that time was ap-

Thursday.....	18	17
Friday.....	18	16
Saturday.....	5	10

proximately 64 percent. In addition, while almost 93 percent of fatal occupational injuries incurred at road construction sites happened on a weekday, just under 84 percent of all workplace fatalities occurred on a weekday. (See table 5.)

Finally, occupational fatalities at road construction sites are more likely to occur between April and October than are occupational fatalities in general. Workplace fatalities at road construction sites during the April–October corridor account for 73 percent of the total, while all workplace fatalities during the April–October corridor account for 62 percent of the total. In 2007, 65 percent of the hours worked in the highway, street, and bridge construction industry were in the April–October corridor.⁹ (See table 6.)

Industry and occupation

Not surprisingly, 500 of those workers fatally injured at road construction sites were working in the construction industry (private and public). Approximately 62 percent of all fatally injured workers were employed in the highway, street, and bridge construction industry. Other notable industries included truck transportation (8 percent), engineering services (2 percent), and utilities (2 percent).

Government workers constituted 14 percent of all fatalities at road construction sites from 2003–07. During that same period, they constituted 9 percent of all workplace fatalities.

Those working in the occupation construction laborers incurred 28 percent of fatal occupational injuries

at road construction sites from 2003 to 2007.¹⁰ In fact, two-thirds of the workers killed at road construction sites were construction-related workers. (See table 7.)

Conclusion

Fatal occupational injuries at road construction sites accounted for 2 percent of all fatal occupational injuries from 2003 to 2007. Workers at road construction sites were often injured by being struck by a vehicle or mobile equipment. In fact, almost 10 percent of the fatalities resulted from a worker being struck by a dump truck that was backing up. Twenty-five cases involved a worker being struck by a vehicle that did not employ a back-up alarm or whose back-up alarm did not alert the worker. Drunk drivers caused the death of 10 workers in road construction sites during the 5-year period. Several entities have made increasing safety at road construction sites a priority.¹¹ □

Table 7. Fatal occupational injuries at road construction sites by occupation, 2003–07

Occupation	Fatalities	Most frequent event
Construction laborer	181	Worker struck by vehicle, mobile equipment (100)
Truck drivers, heavy and tractor trailer.....	76	Highway incident (45)

Notes

ACKNOWLEDGMENT: The author would like to thank Matthew Gunter for his assistance in the preparation of this report.

¹ All data in this analysis are from the Bureau of Labor Statistics (BLS) Census of Fatal Occupational Injuries (CFOI). For more information, see the CFOI homepage on the BLS Web site at <http://www.bls.gov/iif/oshcfoi1.htm>. All data in this report are final. A previous analysis (see note 3) found that the location code for road construction was not being assigned uniformly throughout the data set during this period. Starting in 2003, the CFOI program incorporated a more rigorous examination of road construction site cases that included many of the techniques used in the analysis to identify road construction site cases to ensure that the location code is properly assigned. Because of this enhanced review, no additional case identification measures were undertaken for this analysis. There were, however, a few cases in which the coded data were changed after a review of the case narrative.

² The 2002 North American Industry Classification System (NAICS), which CFOI used to code its 2003–08 data, defines the highway, street, and bridge construction industry as follows: “This industry comprises establishments primarily engaged in the construction of highways (including elevated), streets, roads, airport runways, public sidewalks, or bridges. The

work performed may include new work, reconstruction, rehabilitation, and repairs. Specialty trade contractors are included in this group if they are engaged in activities primarily related to highway, street, and bridge construction (e.g., installing guardrails on highways).” For more information, see the definition for this industry on the 2002 NAICS page of the U.S. Census Bureau Web site at <http://www.census.gov/cgi-bin/sssd/naics/naicsrch?code=237310>.

³ Stephen Pegula, “Fatal occupational injuries at road construction sites,” *Monthly Labor Review*, December 2004, pp. 43–47, on the Internet at <http://www.bls.gov/opub/mlr/2004/12/resum2.pdf>.

⁴ For more information, see *Manual on Uniform Traffic Control Devices for Streets and Highways*, 2009 edition (Federal Highway Administration, December 2009), on the Internet at http://mutcd.fhwa.dot.gov/pdfs/2009/pdf_index.htm (visited Nov. 12, 2010); see page 552 for cited definition.

⁵ This includes both the private and public sector construction industry.

⁶ *Event* is defined using the Occupational Injury and Illness Classification System (OIICS). For more information, see the OIICS page on the BLS Web site at <http://www.bls.gov/iif/oshoiics.htm>.

⁷ OIICS is also used to classify the source of the fatal occupational injury. Construction-related vehicles are defined as dump trucks (source 8252 in OIICS) and construction, logging, and mining

machinery (source category 32*). The construction, logging, and mining machinery category includes backhoes, bulldozers, steam shovels, loaders, scrapers, and pavers.

⁸ These events are separate from the *worker struck by vehicle, mobile equipment*, events noted previously in that these events originate with the worker operating the vehicle, mobile equipment, prior to the incident.

⁹ Hours data are from the Current Employment Statistics (CES) survey and are not seasonally adjusted. The CES uses the 2007 North American Industry Classification System (NAICS) to classify industries. More information on the CES program can be found on the BLS Web site at <http://www.bls.gov/ces/>.

¹⁰ CFOI defines occupations using the 2000 Standard Occupational Classification (SOC) system. For more information, see the SOC (2000) page on the BLS Web site at <http://www.bls.gov/soc/2000/socguide.htm>.

¹¹ For more information on safety measures at road construction sites, see Workplace Safety & Health Topics, National Institute of Occupational Safety and Health (NIOSH), Centers for Disease Control and Prevention, on the Internet at <http://www.cdc.gov/niosh/topics/highway-workzones/>; also, the National Work Zone Safety Information Clearinghouse, on the Internet at <http://www.workzonesafety.org/> (visited Nov. 12, 2010).

Immigration and the U.S. economy

Throughout U.S. history, the tide of immigrants has ebbed and flowed—mostly flowed, lest the Nation have remained a relatively thinly populated realm on the North American continent. But the question of the effect of immigrants on the economy has vexed economists at least since the shift of the United States from an agricultural and manufacturing powerhouse to a more service-oriented economy began in earnest during the 1960s and 1970s. For some time now, the popular press has posed the issue as whether immigrants take jobs away from U.S.-born workers or whether they occupy an essential economic niche, performing jobs that U.S.-born workers shun. Rather than address this emotionally charged issue specifically, Giovanni Peri seeks to learn whether the aggregate effect of immigrants on the U.S. economy (including the effect on U.S.-born workers) was positive or negative from 1960 to 2008.

In “The Effect of Immigrants on U.S. Employment and Productivity” (Federal Reserve Bank of San Francisco, *FRBSF Economic Letter*, Aug. 30, 2010), Peri summarizes his own recent research, and research that he has undertaken with a colleague (Chad Sparber), showing that the economic effect of immigrants on U.S.-born workers has been mostly positive. Specifically, (1) for the period from 1960 to 2008, no statistically significant effect of immigrants on the net job growth of U.S.-born workers was found, suggesting that “the economy absorbs immigrants by expanding job opportunities

rather than by displacing workers born in the United States”; (2) there is a short-term negative effect in which the capital intensity of the economy is reduced as businesses try to adjust their productive capacity (equipment and structures) to make use of the immigrants, followed by positive medium- and long-term effects wherein, after businesses have made the adjustment, output per worker increases; and (3) immigration is associated with the two offsetting effects of an increase in average hours per worker and a decrease in the average level of skill per worker.

In carrying out the research, the author and his colleagues were of course faced with the challenge of identifying the effects of immigration on the economy without knowing what would have happened if immigration levels had been different. To circumvent this obstacle, they used State-level differences in immigration growth to estimate short-, medium-, and long-term effects of the impact of immigrants on output, income, and employment. That is, the different influxes of immigrants across States since 1960 served as a proxy for counterfactual levels of immigration. At the same time, the authors controlled for (1) non-immigrant-related variables that might have contributed to differences in economic outcomes and (2) State-specific effects that may have attracted immigrants, but only incidentally, because they attracted migrants in general to the State. Toward the latter end, the authors focused on historical and geographical factors (for example, proximity to the U.S.–Mexican border) unrelated to State-specific economic conditions.

The chief finding of the research was that there is no evidence that immigrants are having a deleterious effect on the U.S. economy. Statistical tests showed that both employment and hours per worker were unaffected in the short term by the hiring of immigrants. Even more, in the long term, employment remained unaffected while hours per worker actually grew slightly. The lone negative effect was that, in both the short and long term, the average skill level of workers was reduced somewhat, because immigrants’ education levels are, on average, lower than those of U.S.-born workers.

A second finding was that immigration was associated with an *increase* in the average income of U.S. workers over the long term. (No significant effects on income were observed in the short term.) Specifically, a 1-percent rise in immigration resulted in an increase of 0.6 percent to 0.9 percent in income per worker, meaning that total immigration to the United States from 1990 to 2007 produced a 6.6-percent to 9.9-percent increase in workers’ income. In dollar terms, those percentages translate into a gain of about \$5,100 in the annual income of the average U.S. worker, in constant 2005 dollars, or 20 percent to 25 percent of the total real increase in average yearly income per worker between 1990 and 2007.

Finally, the author concludes that the long-term growth in income per worker attributable to immigrants is due mainly to increases in efficiency and productivity. Tests of physical capital intensity, skill intensity, average hours worked, and total factor productivity show that, although in the short term net immigration

decreases physical capital (the resources used to produce goods and services) per unit of output, in the medium-to-long term businesses expand their equipment and plants

to accommodate increases in production attributable to the hiring of immigrants. According to Peri, in effect, businesses make adjustments, first hiring immigrants in

the short term and then upgrading and expanding their capital stock in the long term, to take full advantage of the new labor supply that immigrants offer. □

Where are you publishing your research?

The *Monthly Labor Review* welcomes articles on the labor force, labor-management relations, business conditions, industry productivity, compensation, occupational safety and health, demographic trends, and other economic developments. Papers should be factual and analytical, not polemical, in tone. For guidelines on how to submit papers, go to www.bls.gov/opub/mlr/guidelines.htm. Potential articles, as well as comments on material published in the *Review*, should be submitted to:

Airline industry future “up in the air”

Up in the Air: How airlines can improve performance by engaging their employees. By Greg Bamber, Jody Hoffer Gittel, Thomas A. Kochan, and Andrew von Nordenflycht. Ithaca, NY, Cornell University Press, 2009, 222 pp., \$29.95/cloth.

Most of us travel by airline at least occasionally. Even though the vast majority of flights could be considered successful, the number of complaints has risen significantly. The level of frustration has increased to the point that it is the subject of countless jokes from humorists. And whenever there is an accident or terrorist incident, it can scare customers away whether or not the airline is at fault.

The airline industry employs hundreds of thousands of people and is extremely important to this nation and others. Unfortunately, a variety of problems have confronted the industry over the past half century. In addition to customer complaints, these include more intense competition and safety concerns. As a result, profitability has been elusive for most airlines; despite cost-cutting measures and mergers, airlines still seem to go into bankruptcy regularly.

In a word, the airline industry is in trouble.

What can airlines do in this new environment to overcome the obstacles and move toward sustainable profits? That is the subject of *Up in the Air*; to explain how the industry got to this point and what can be done to make it profitable. The central thesis, backed up with strong evidence, is that employee and customer satisfaction can co-exist with

increased revenue and profits.

The year 1978 was a significant dividing point in airline history in the United States: the start of deregulation. Prior to 1978 airlines competed on a service basis rather than a cost basis, keeping revenues artificially high and weakening incentives to lower costs. Federal law to that point defined occupational groups for collective bargaining purposes; for the airline industry this meant union agreements with a variety of unions rather than just one. As a result, a strike by one union could easily result in a complete shutdown of the airline, as other unions would honor the striking union's picket lines. Consequently, airlines tended to agree to high wages and generous benefits rather than risk a strike.

Deregulation had an immediate and dramatic effect. Low-cost airlines sprang up all over the country and these new entrants provided lower cost fares than the “legacy” airlines. Better service was no longer enough; legacy airlines had to offer lower prices—if not as low as the discount airlines then at least approaching them. This led to layoffs and tougher bargaining positions for wages and benefits; in some cases, unions had to agree to lower wages in order to keep jobs. The good news for the consumer was substantially lower prices (about half the price per mile than pre-1978), but the bad news was a period of chaos that continues today.

The years following deregulation saw mergers as a strategy to survive. Mergers can help to reduce costs by creating economies of scale but the primary intent of mergers is to reduce competition. When two airlines merge, they combine staffs and consolidate routes. When there are

fewer routes, customers have fewer options and prices tend to go up—at least in theory.

The period between 1978 and the present has seen volatility in airlines' earnings. The industry as a whole experienced either modest profits or slight losses, but some airlines did better than others. There was a substantial boom in the mid-1990s followed by an even deeper bust later in the decade and early 2000s, followed by substantial gains from 2003 to 2008. The event that changed everything for the United States—9/11—had an even more profound effect on airlines. The terrorist attacks led to an immediate decline in airline travel, plus new security rules that made flying less convenient. Almost nine years later, there are airlines that have not completely recovered from the shock of 9/11 and others that did not survive the immediate effects.

The authors analyze the events over the turbulent past 40 years and find patterns that are instructive. Different airlines employed different strategies for dealing with the turmoil. One of the major focuses is labor-management relations. For new entrant airlines, the authors categorize two aspects: management's interaction with employees and management's approach to unions. The authors further define two categories of employee interaction: *control* and *commitment* and three categories of union relations: *avoid*, *accommodate*, and *partner*. This analysis leads to a six-cell matrix representing all the possibilities. The authors, using interviews with airline and union representatives as well as other materials, categorize new-entrant airlines into one of the six cells. For example, one airline

is considered to have a *commitment* (to employees)-*partner* (with union) approach. At the other extreme, two airlines are considered *control-avoid*. The authors demonstrate that avoiding unions and controlling employees do not necessarily lead to sustainable profits. Conversely, the *commitment-partner* airline has had consistent profitability, higher customer and employee satisfaction, few customer complaints, and has never had a layoff.

Up in the Air uses statistics and anecdotes effectively. There are many tables and charts, but they

are simple and usually easy to understand. There are also interviews with leading industry experts and company officials as well as stories of successes and failures. For example, the authors describe how one airline encourages teamwork and some blurring of occupational distinctions among workers to increase productivity.

The authors' coverage of the U.S. Airline industry is quite comprehensive; reporting on airlines outside the United States is less so. Central and Western Europe are covered extensively and Asia to some extent,

but there is little or no mention of the rest of the Americas, Eastern Europe, or sub-Saharan Africa.

Up in the Air is an informative, balanced, well-researched, astute, and instructive treatise on the airline industry. The book is quite accessible to readers who are neither economists nor familiar with the industry. The authors' suggestions are meaningful for the airlines and can be applied to other industries as well. I recommend it. □

Nominations Sought for 2011 Julius Shiskin Award

Nominations are invited for the annual Julius Shiskin Memorial Award for Economic Statistics. The Award is given in recognition of unusually original and important contributions in the development of economic statistics or in the use of statistics in interpreting the economy. Contributions are recognized for statistical research, development of statistical tools, application of information technology techniques, use of economic statistical programs, management of statistical programs, or developing public understanding of measurement issues. The Award was established in 1980 by the Washington Statistical Society (WSS) and is now cosponsored by the WSS, the National Association for Business Economics, and the Business and Economics Statistics Section of the American Statistical Association (ASA). The 2010 award recipient was Dr. Dale W. Jorgenson for his contributions to the measurement of productivity, innovation, capital, human capital, poverty, and for his leadership in the integration of the U.S. National Accounts.

Because the program was initiated many years ago, statisticians and economists often ask, "Who was Julius Shiskin?" At the time of his death in 1978, "Julie" was the Commissioner for the Bureau of Labor Statistics (BLS) and earlier served as the Chief Statistician at the Office of Management and Budget (OMB), and the Chief Economic Statistician and Assistant Director of the Census Bureau. Throughout his career, he was known as an innovator. At Census he was instrumental in developing an electronic computer method for seasonal adjustment. In 1961, he published *Signals of Recession and Recovery*, which laid the groundwork for the calculation of monthly economic indicators, and he developed the monthly Census report *Business Conditions Digest* to disseminate them to the public. In 1969, he was appointed Chief Statistician at OMB where he developed the policies and procedures that govern the release of key economic indicators (Statistical Policy Directive Number 3), and originated a Social Indicators report. In 1973, he was selected to head BLS where he was instrumental in preserving the integrity and independence of the BLS labor force data and directed the most comprehensive revision in the history of the Consumer Price Index (CPI), which included a new CPI for all urban consumers.

Nominations for the 2011 award are now being accepted. Individuals and groups in the public or private sector from any country can be nominated. The award will be presented with an honorarium of \$1000 plus additional recognition from the sponsors. A nomination form and a list of all previous recipients are available on the ASA Website at www.amstat.org/sections/bus_econ/shiskin.html.

For questions or more information, please contact Steven Paben, Julius Shiskin Award Committee Secretary, via e-mail at paben.steven@bls.gov or call 202-691-6147.

Completed nominations must be received by March 15, 2011.

55. Fatal occupational injuries by event or exposure 121

Notes on Current Labor Statistics

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as “seasonally adjusted.” (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables 1–14, 17–21, 48, and 52. Seasonally adjusted labor force data in tables 1 and 4–9 and seasonally adjusted establishment survey data shown in tables 1, 12–14, and 17 usually are revised in the March issue of the *Review*. A brief explanation of the seasonal adjustment methodology appears in “Notes on the data.”

Revisions in the productivity data in table 54 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All-Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the “real” earnings shown in table 14—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of \$3 and a current price index number of 150, where 1982 = 100, the hourly rate expressed in 1982 dollars is \$2 ($\$3/150 \times 100 = \2). The \$2 (or any other resulting

values) are described as “real,” “constant,” or “1982” dollars.

Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see *BLS Handbook of Methods*, Bulletin 2490. Users also may wish to consult *Major Programs of the Bureau of Labor Statistics*, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau’s monthly publication, *Employment and Earnings*. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:

www.bls.gov/cps/

Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:

www.bls.gov/ces/

Additional information on labor force data for areas below the national level are provided in the BLS annual report, *Geographic Profile of Employment and Unemployment*.

For a comprehensive discussion of the Employment Cost Index, see *Employment Cost Indexes and Levels, 1975–95*, BLS Bulletin 2466. The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: *Employee Benefits in Medium and Large Firms*; *Employee Benefits in Small Private Establishments*; and *Employee Benefits in State and Local Governments*.

More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report* and *Producer Price Indexes*. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the *Monthly Labor Review*. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

www.bls.gov/lpc/

For additional information on international comparisons data, see *International Comparisons of Unemployment*, Bulletin

1979.

Detailed data on the occupational injury and illness series are published in *Occupational Injuries and Illnesses in the United States, by Industry*, a BLS annual bulletin.

Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

n.e.c. = not elsewhere classified.

n.e.s. = not elsewhere specified.

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.

r = revised. Generally, this revision reflects the availability of later data, but also may reflect other adjustments.

Comparative Indicators

(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population (“household”) Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index

program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

Employment and Unemployment Data

(Tables 1; 4–29)

Household survey data

Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work

because they were on layoff are also counted among the unemployed. **The unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population. Persons **not in the labor force** are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The **civilian noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The **civilian labor force participation rate** is the proportion of the civilian noninstitutional population that is in the labor force. The **employment-population ratio** is employment as a percent of the civilian noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of *Employment and Earnings*. For a discussion of changes introduced in January 2003, see "Revisions to the Current Population Survey Effective in January 2003" in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at www.bls.gov/cps/rvcps03.pdf).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See "Revision of Seasonally Adjusted Labor Force Series in 2003," in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at www.bls.gov/cps/cpsrs.pdf) for a discussion of the introduction of the use of X-12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the January–June period. The historical season-

ally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July–December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691–6378.

Establishment survey data

Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2007 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goods-producing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private service-providing industries, data are collected for nonsupervisory workers, which include most employees except those in executive, managerial, and supervisory positions. Those

workers mentioned in tables 11–16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private service-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours.

Overtime hours represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The **Diffusion Index** represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

Notes on the data

With the release of data for January 2010, the CES program introduced its annual revision of national estimates of employment, hours, and earnings from the monthly survey of nonfarm establishments. Each year, the CES survey realigns its sample-based estimates to incorporate universe counts of employment—a process known as benchmarking. Comprehensive counts of employment, or benchmarks, are derived primarily from unemployment insurance (UI) tax reports that nearly all employers are required to file with State Workforce Agencies. With the release in June 2003, CES completed the transition from its original quota sample design to a

probability-based sample design. The industry-coding update included reconstruction of historical estimates in order to preserve time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the June 2003 issue of *Employment and Earnings* and “Recent changes in the national Current Employment Statistics survey,” *Monthly Labor Review*, June 2003, pp. 3–13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of *Employment and Earnings*, and “Recent changes in the State and Metropolitan Area CES survey,” *Monthly Labor Review*, June 2003, pp. 14–19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4- versus 5-week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12–17 in the *Review*). When all returns have been received, the estimates are revised and published as “final” (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Fourth-quarter data are pub-

lished as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on establishment survey data, contact the Division of Current Employment Statistics: (202) 691–6555.

Unemployment data by State

Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691–6392 (table 10) or (202) 691–6559 (table 11).

Quarterly Census of Employment and Wages

Description of the series

Employment, wage, and establishment data in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal, agencies subject to the Unemployment Compensation for Federal Employees (UCFE) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Quarterly Census of Employment and Wages (QCEW) data, also referred as ES-202 data, are the most complete enumeration of employment and wage information by

industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor market trends and major industry developments.

Definitions

In general, the Quarterly Census of Employment and Wages monthly employment data represent the number of **covered workers** who worked during, or received pay for, the pay period that included the 12th day of the month. **Covered private industry employment** includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each ui-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (UCFE) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An **establishment** is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different NAICS industries.

Most employers have only one establishment; thus, the establishment is the

predominant reporting unit or statistical entity for reporting employment and wages data. Most employers, including State and local governments who operate more than one establishment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly ui report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the ui report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the **installation**: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers. Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into **size** categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level. It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total **wages** paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify

that wages be reported for, or based on the period during which services are performed rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as 401(k) plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wage per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual wage is affected by the ratio of full-time to part-time workers as well as the number of individuals in high-paying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of part-time workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

Notes on the data

Beginning with the release of data for 2007, publications presenting data from the Covered Employment and Wages program have

switched to the 2007 version of the North American Industry Classification System (NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Standard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past, the Covered Employment and Wage (CEW) program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England (and New Jersey).

The Office of Management and Budget (OMB) defines metropolitan areas for use in Federal statistical activities and updates these definitions as needed. Data in this table use metropolitan area criteria established by OMB in definitions issued June 30, 1999 (OMB Bulletin No. 99-04). These definitions reflect information obtained from the 1990 Decennial Census and the 1998 U.S. Census Bureau population estimate. A complete list of metropolitan area definitions is available from the National Technical Information Service (NTIS), Document Sales, 5205 Port Royal Road, Springfield, Va. 22161, telephone 1-800-553-6847.

OMB defines metropolitan areas in terms of entire counties, except in the six New England States where they are defined in terms of cities and towns. New England data in this table, however, are based on a county concept defined by OMB as New England County Metropolitan Areas (NECMA) because county-level data are the most detailed available from the Quarterly Census of Employment and Wages. The NECMA is a county-based alternative to the city- and town-based metropolitan areas in New England. The NECMA for a Metropolitan Statistical Area (MSA) include: (1) the county containing the first-named city in that MSA title (this county may include the first-named cities of other MSA, and (2) each additional county having at least half its population in the MSA in which first-named cities are in the county identified in step 1. The NECMA is officially defined areas that are meant to be used by statistical programs that cannot use the regular metropolitan area definitions in New England.

FOR ADDITIONAL INFORMATION on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691-6567.

Job Openings and Labor Turnover Survey

Description of the series

Data for the **Job Openings and Labor Turnover Survey** (JOLTS) are collected and compiled from a sample of 16,000 business establishments. Each month, data are collected for total employment, job openings, hires, quits, layoffs and discharges, and other separations. The JOLTS program covers all private nonfarm establishments such as factories, offices, and stores, as well as Federal, State, and local government entities in the 50 States and the District of Columbia. The JOLTS sample design is a random sample drawn from a universe of more than eight mil-

lion establishments compiled as part of the operations of the Quarterly Census of Employment and Wages, or QCEW, program. This program includes all employers subject to State unemployment insurance (UI) laws and Federal agencies subject to Unemployment Compensation for Federal Employees (UCFE).

The sampling frame is stratified by ownership, region, industry sector, and size class. Large firms fall into the sample with virtual certainty. JOLTS total employment estimates are controlled to the employment estimates of the Current Employment Statistics (CES) survey. A ratio of CES to JOLTS employment is used to adjust the levels for all other JOLTS data elements. Rates then are computed from the adjusted levels.

The monthly JOLTS data series begin with December 2000. Not seasonally adjusted data on job openings, hires, total separations, quits, layoffs and discharges, and other separations levels and rates are available for the total nonfarm sector, 16 private industry divisions and 2 government divisions based on the North American Industry Classification System (NAICS), and four geographic regions. Seasonally adjusted data on job openings, hires, total separations, and quits levels and rates are available for the total nonfarm sector, selected industry sectors, and four geographic regions.

Definitions

Establishments submit **job openings** information for the last business day of the reference month. A job opening requires that (1) a specific position exists and there is work available for that position; and (2) work could start within 30 days regardless of whether a suitable candidate is found; and (3) the employer is actively recruiting from outside the establishment to fill the position. Included are full-time, part-time, permanent, short-term, and seasonal openings. Active recruiting means that the establishment is taking steps to fill a position by advertising in newspapers or on the Internet, posting help-wanted signs, accepting applications, or using other similar methods.

Jobs to be filled only by internal transfers, promotions, demotions, or recall from layoffs are excluded. Also excluded are jobs with start dates more than 30 days in the future, jobs for which employees have been hired but have not yet reported for work, and jobs to be filled by employees of temporary help agencies, employee leasing companies, outside contractors, or consultants. The job openings rate is computed by dividing the number of job openings by the sum of employment and job openings, and multiplying that quotient

by 100.

Hires are the total number of additions to the payroll occurring at any time during the reference month, including both new and rehired employees and full-time and part-time, permanent, short-term and seasonal employees, employees recalled to the location after a layoff lasting more than 7 days, on-call or intermittent employees who returned to work after having been formally separated, and transfers from other locations. The hires count does not include transfers or promotions within the reporting site, employees returning from strike, employees of temporary help agencies or employee leasing companies, outside contractors, or consultants. The hires rate is computed by dividing the number of hires by employment, and multiplying that quotient by 100.

Separations are the total number of terminations of employment occurring at any time during the reference month, and are reported by type of separation—quits, layoffs and discharges, and other separations. Quits are voluntary separations by employees (except for retirements, which are reported as other separations). Layoffs and discharges are involuntary separations initiated by the employer and include layoffs with no intent to rehire, formal layoffs lasting or expected to last more than 7 days, discharges resulting from mergers, downsizing, or closings, firings or other discharges for cause, terminations of permanent or short-term employees, and terminations of seasonal employees. Other separations include retirements, transfers to other locations, deaths, and separations due to disability. Separations do not include transfers within the same location or employees on strike.

The separations rate is computed by dividing the number of separations by employment, and multiplying that quotient by 100. The quits, layoffs and discharges, and other separations rates are computed similarly, dividing the number by employment and multiplying by 100.

Notes on the data

The JOLTS data series on job openings, hires, and separations are relatively new. The full sample is divided into panels, with one panel enrolled each month. A full complement of panels for the original data series based on the 1987 Standard Industrial Classification (SIC) system was not completely enrolled in the survey until January 2002. The supplemental panels of establishments needed to create NAICS estimates were not completely enrolled until May 2003. The data collected up until those points are from less than a

full sample. Therefore, estimates from earlier months should be used with caution, as fewer sampled units were reporting data at that time.

In March 2002, BLS procedures for collecting hires and separations data were revised to address possible underreporting. As a result, JOLTS hires and separations estimates for months prior to March 2002 may not be comparable with estimates for March 2002 and later.

The Federal Government reorganization that involved transferring approximately 180,000 employees to the new Department of Homeland Security is not reflected in the JOLTS hires and separations estimates for the Federal Government. The Office of Personnel Management's record shows these transfers were completed in March 2003. The inclusion of transfers in the JOLTS definitions of hires and separations is intended to cover ongoing movements of workers between establishments. The Department of Homeland Security reorganization was a massive one-time event, and the inclusion of these intergovernmental transfers would distort the Federal Government time series.

Data users should note that seasonal adjustment of the JOLTS series is conducted with fewer data observations than is customary. The historical data, therefore, may be subject to larger than normal revisions. Because the seasonal patterns in economic data series typically emerge over time, the standard use of moving averages as seasonal filters to capture these effects requires longer series than are currently available. As a result, the stable seasonal filter option is used in the seasonal adjustment of the JOLTS data. When calculating seasonal factors, this filter takes an average for each calendar month after detrending the series. The stable seasonal filter assumes that the seasonal factors are fixed; a necessary assumption until sufficient data are available. When the stable seasonal filter is no longer needed, other program features also may be introduced, such as outlier adjustment and extended diagnostic testing. Additionally, it is expected that more series, such as layoffs and discharges and additional industries, may be seasonally adjusted when more data are available.

JOLTS hires and separations estimates cannot be used to exactly explain net changes in payroll employment. Some reasons why it is problematic to compare changes in payroll employment with JOLTS hires and separations, especially on a monthly basis, are: (1) the reference period for payroll employment is the pay period including the 12th of the month, while the reference period for hires and separations is the calendar month; and (2) payroll employment can vary from month

to month simply because part-time and on-call workers may not always work during the pay period that includes the 12th of the month. Additionally, research has found that some reporters systematically underreport separations relative to hires due to a number of factors, including the nature of their payroll systems and practices. The shortfall appears to be about 2 percent or less over a 12-month period.

FOR ADDITIONAL INFORMATION on the Job Openings and Labor Turnover Survey, contact the Division of Administrative Statistics and Labor Turnover at (202) 961-5870.

Compensation and Wage Data

(Tables 1-3; 30-37)

The National Compensation Survey (NCS) produces a variety of compensation data. These include: The Employment Cost Index (ECI) and NCS benefit measures of the incidence and provisions of selected employee benefit plans. Selected samples of these measures appear in the following tables. NCS also compiles data on occupational wages and the Employer Costs for Employee Compensation (ECEC).

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It is a Laspeyres Index that uses fixed employment weights to measure change in labor costs free from the influence of employment shifts among occupations and industries.

The ECI provides data for the civilian economy, which includes the total private nonfarm economy excluding private households, and the public sector excluding the Federal government. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Sample establishments are classified by industry categories based on the 2007 North American Classification System (NAICS). Within a sample establishment, specific job categories are selected and classified into about 800 occupations according to the 2000 Standard Occupational Classification (SOC) System. Individual occupations are combined to represent one of ten intermediate

aggregations, such as professional and related occupations, or one of five higher level aggregations, such as management, professional, and related occupations.

Fixed employment weights are used each quarter to calculate the most aggregate series—civilian, private, and State and local government. These fixed weights are also used to derive all of the industry and occupational series indexes. Beginning with the March 2006 estimates, 2002 fixed employment weights from the Bureau's Occupational Employment Statistics survey were introduced. From March 1995 to December 2005, 1990 employment counts were used. These fixed weights ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the series based on bargaining status, census region and division, and metropolitan area status, fixed employment data are not available. The employment weights are reallocated within these series each quarter based on the current ECI sample. The indexes for these series, consequently, are not strictly comparable with those for aggregate, occupational, and industry series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The ECI data in these tables reflect the conversion to the 2002 North American Industry Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. ECI series based on NAICS and SOC became the official BLS estimates starting in March 2006.

The ECI for changes in wages and salaries in the private nonfarm economy was pub-

lished beginning in 1975. Changes in total compensation cost—wages and salaries and benefits combined—were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (December 2005=100) are available on the Internet: www.bls.gov/ect/

ADDITIONAL INFORMATION on the Employment Cost Index is available at www.bls.gov/ncs/ect/home.htm or by telephone at (202) 691-6199.

National Compensation Survey Benefit Measures

Description of the series

NCS benefit measures of employee benefits are published in two separate reports. The annual summary provides data on the incidence of (access to and participation in) selected benefits and provisions of paid holidays and vacations, life insurance plans, and other selected benefit programs. Data on percentages of establishments offering major employee benefits, and on the employer and employee shares of contributions to medical care premiums also are presented. Selected benefit data appear in the following tables. A second publication, published later, contains more detailed information about health and retirement plans.

Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Employees are considered as having **access** to a benefit plan if it is available for their use. For example, if an employee is permitted to participate in a medical care plan offered by the employer, but the employee declines to do so, he or she is placed in the category with those having access to medical care.

Employees in contributory plans are considered as **participating** in an insurance or retirement plan if they have paid required contributions and fulfilled any applicable

service requirement. Employees in noncontributory plans are counted as participating regardless of whether they have fulfilled the service requirements.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

Notes on the data

ADDITIONAL INFORMATION on the NCS benefit measures is available at www.bls.gov/ncs/cbs/home.htm or by telephone at (202) 691-6199.

Work stoppages

Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 37.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved

in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

ADDITIONAL INFORMATION on work stoppages data is available at www.bls.gov/cba/home.htm or by telephone at (202) 691-6199.

Price Data

(Tables 2; 38-46)

Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period—December 2003 = 100 for many Producer Price Indexes (unless otherwise noted), 1982-84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 = 100 for International Price Indexes.

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993-95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 14 major urban centers are presented in table 39. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691-7000.

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in accordance with the North American Indus-

try Classification System and product codes developed by the U.S. Census Bureau.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691-7705.

International Price Indexes

Description of the series

The **International Price Program** produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during

the first week of the month. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard International Trade Classification (SITC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691-7155.

Productivity Data

(Tables 2; 47–50)

Business and major sectors

Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour,

output per unit of labor input, or output per unit of capital input, as well as measures of multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input.

Output per unit of capital services (capital productivity) is the quantity of goods and services produced per unit of capital services input. **Multifactor productivity** is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It

is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 47–50 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity; energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

Industry productivity measures

Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, **output** indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The **labor input** series is based on the hours of all workers or, in the case of some transportation industries, on the number of employees. For most industries, the series consists of the hours of all employees. For some trade and services industries, the series also includes the hours of partners, proprietors, and unpaid family workers.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. **Labor compensation** includes payroll as well as supplemental payments, including both legally required expenditures and payments for voluntary programs.

Multifactor productivity is derived by dividing an index of industry output by an index of combined inputs consumed in producing that output. **Combined inputs** include capital, labor, and intermediate purchases. The measure of **capital input** represents the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories. The measure of **intermediate purchases** is a combination of purchased materials, services, fuels, and electricity.

Notes on the data

The industry measures are compiled from data produced by the Bureau of Labor Statistics and the Census Bureau, with additional data supplied by other government agencies, trade associations, and other sources.

International Comparisons

(Tables 51–53)

Labor force and unemployment

Description of the series

Tables 51 and 52 present comparative measures of the labor force, employment, and unemployment approximating U.S. concepts for the United States, Canada, Australia, Japan, and six European countries. The Bureau adjusts the figures for these selected countries, for all known major definitional differences, to the extent that data to prepare adjustments are available. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For further information on adjustments and comparability issues, see Constance Sorrentino, “International unemployment rates: how comparable are they?” *Monthly Labor Review*, June 2000, pp. 3–20, available on the Internet at www.bls.gov/opub/mlr/2000/06/art1full.pdf.

Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

Notes on the data

Foreign country data are adjusted as closely as possible to the U.S. definitions. Primary areas of adjustment address conceptual differences in upper age limits and definitions of employment and unemployment, provided that reliable data are available to make these adjustments. Adjustments are made where applicable to include employed and unemployed persons above upper age limits; some European countries do not include persons older than age 64 in their labor force measures, because a large portion

of this population has retired. Adjustments are made to exclude active duty military from employment figures, although a small number of career military may be included in some European countries. Adjustments are made to exclude unpaid family workers who worked fewer than 15 hours per week from employment figures; U.S. concepts do not include them in employment, whereas most foreign countries include all unpaid family workers regardless of the number of hours worked. Adjustments are made to include full-time students seeking work and available for work as unemployed when they are classified as not in the labor force.

Where possible, lower age limits are based on the age at which compulsory schooling ends in each country, rather than based on the U.S. standard of 16. Lower age limits have ranged between 13 and 16 over the years covered; currently, the lower age limits are either 15 or 16 in all 10 countries.

Some adjustments for comparability are not made because data are unavailable for adjustment purposes. For example, no adjustments to unemployment are usually made for deviations from U.S. concepts in the treatment of persons waiting to start a new job or passive job seekers. These conceptual differences have little impact on the measures. Furthermore, BLS studies have concluded that no adjustments should be made for persons on layoff who are counted as employed in some countries because of their strong job attachment as evidenced by, for example, payment of salary or the existence of a recall date. In the United States, persons on layoff have weaker job attachment and are classified as unemployed.

The annual labor force measures are obtained from monthly, quarterly, or continuous household surveys and may be calculated as averages of monthly or quarterly data. Quarterly and monthly unemployment rates are based on household surveys. For some countries, they are calculated by applying annual adjustment factors to current published data and, therefore, are less precise indicators of unemployment under U.S. concepts than the annual figures. The labor force measures may have breaks in series over time due to changes in surveys, sources, or estimation methods. Breaks are noted in data tables.

For up-to-date information on adjustments and breaks in series, see the Technical Notes of *Comparative Civilian Labor Force Statistics, 10 Countries*, on the Internet at www.bls.gov/fls/flscomparelf.htm, and the Notes of *Unemployment rates in 10 countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted*, on the Internet at www.bls.gov/fls/flsjec.pdf.

this series, contact the Division of Foreign Labor Statistics: (202) 691-5654 or flshelp@bls.gov.

Manufacturing productivity and labor costs

Description of the series

Table 53 presents comparative indexes of manufacturing output per hour (labor productivity), output, total hours, compensation per hour, and unit labor costs for the United States, Australia, Canada, Japan, the Republic of Korea, Singapore, Taiwan, and 10 European countries. These measures are trend comparisons—that is, series that measure changes over time—rather than level comparisons. BLS does *not* recommend using these series for level comparisons because of technical problems.

BLS constructs the comparative indexes from three basic aggregate measures—output, total labor hours, and total compensation. The hours and compensation measures refer to employees (wage and salary earners) in Belgium and Taiwan. For all other economies, the measures refer to all employed persons, including employees, self-employed persons, and unpaid family workers.

The data for recent years are based on the United Nations System of National Accounts 1993 (SNA 93). Manufacturing is generally defined according to the International Standard Industrial Classification (ISIC). However, the measures for France include parts of mining as well. For the United States and Canada, manufacturing is defined according to the North American Industry Classification System.

Definitions

Output. For most economies, the output measures are real value added in manufacturing from national accounts. However, output for Japan prior to 1970 and for the Netherlands prior to 1960 are indexes of industrial production. The manufacturing value added measures for the United Kingdom are essentially identical to their indexes of industrial production.

For United States, the output measure for the manufacturing sector is a chain-weighted index of real gross product originating (deflated value added) produced by the Bureau of Economic Analysis of the U.S. Department of Commerce. Most of the other economies now also use chain-weighted as opposed to fixed-year weights that are periodically updated.

To preserve the comparability of the U.S.

measures with those of other economies, BLS uses gross product originating in manufacturing for the United States. The gross product originating series differs from the manufacturing output series that BLS publishes in its quarterly news releases on U.S. productivity and costs (and that underlies the measures that appear in tables 48 and 50 in this section). The quarterly measures are on a “sectoral output” basis, rather than a value-added basis. Sectoral output is gross output less intrasector transactions.

Total hours refer to hours worked in all economies. The measures are developed from statistics of manufacturing employment and average hours. For most other economies, recent years’ aggregate hours series are obtained from national statistical offices, usually from national accounts. However, for some economies and for earlier years, BLS calculates the aggregate hours series using employment figures published with the national accounts, or other comprehensive employment series, and data on average hours worked.

Hourly compensation is total compensation divided by total hours. Total compensation includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. For Australia, Canada, France, Singapore, and Sweden, compensation is increased to account for important taxes on payroll or employment. For the United Kingdom, compensation is reduced between 1967 and 1991 to account for subsidies.

Labor productivity is defined as real output per hour worked. Although the labor productivity measure presented in this release relates output to the hours worked of persons employed in manufacturing, it does not measure the specific contributions of labor as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology, capital investment, capacity utilization, energy use, and managerial skills, as well as the skills and efforts of the workforce.

Unit labor costs are defined as the cost of labor input required to produce one unit of output. They are computed as compensation in nominal terms divided by real output. Unit labor costs can also be computed by dividing hourly compensation by output per hour, that is, by labor productivity.

Notes on the data

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national ac-

counts and other statistics used for the long-term measures become available.

FOR ADDITIONAL INFORMATION on this series, go to <http://www.bls.gov/news.release/prod4.toc.htm> or contact the Division of International Labor Comparison at (202) 691-5654.

Occupational Injury and Illness Data

(Tables 54–55)

Survey of Occupational Injuries and Illnesses

Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers’ job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or

days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both, because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

Notes on the data

The definitions of occupational injuries and illnesses are from *Recordkeeping Guidelines for Occupational Injuries and Illnesses* (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal

tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, *Occupational Injuries and Illnesses: Counts, Rates, and Characteristics*.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691-6180, or access the Internet at: www.bls.gov/iif/

Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers'

compensation reports, Occupational Safety and Health Administration and Mine Safety and Health Administration records, medical examiner and autopsy reports, media accounts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

Definition

A **fatal work injury** is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses, which can be difficult to identify due to long latency periods.

Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 691-6175, or the Internet at: www.bls.gov/iif/

¹ Quarterly data seasonally adjusted.

² Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter.

³ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

⁴ Excludes Federal and private household workers.

⁵ Goods-producing industries include mining, construction, and manufacturing. Service-providing industries include all other private sector industries.

NOTE: Beginning in January 2003, household survey data reflect revised population controls. Nonfarm data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with SIC-based data.

¹ Seasonally adjusted. "Quarterly average" is percent change from a quarter ago, at an annual rate.

² The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard

Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

³ Excludes Federal and private household workers.

4. Employment status of the population, by sex, age, race, and Hispanic origin, monthly data seasonally adjusted

The population figures are not seasonally adjusted.

Civilian employment as a percent of the civilian noninstitutional population.

Beginning in 2003, persons who selected this race group only; persons who selected more than one race group are not included. Prior to 2003, persons who reported more than one race were included in the group they identified as the main race.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in January 2003, data reflect revised population controls used in the household survey.

¹ Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs.

² Includes data for Metropolitan Statistical Areas (MSA) as defined by OMB Bulletin No. 04-03 as of February 18, 2004.

³ Each year's total is based on the MSA definition for the specific year. Annual changes include differences resulting from changes in MSA definitions.

⁴ Totals do not include the six MSAs within Puerto Rico.

¹ Cost (cents per hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

² Consists of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

³ Consists of legislative, judicial, administrative, and regulatory activities.

NOTE: The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

¹ The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC) System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.

² The white-collar and blue-collar occupation series were discontinued effective 2007.

³ The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.

Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

¹ Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:
M—Every month.

1—January, March, May, July, September, and November.

2—February, April, June, August, October, and December.

² Regions defined as the four Census regions.

³ Indexes on a December 1996 = 100 base.

⁴ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.

⁵ Indexes on a December 1986 = 100 base.

⁶ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the *CPI Detailed*

Report: Anchorage, AK; Cincinnati, OH—KY—IN; Kansas City, MO—KS; Milwaukee—Racine, WI; Minneapolis—St. Paul, MN—WI; Pittsburgh, PA; Portland—Salem, OR—WA; St. Louis, MO—IL; San Diego, CA; Tampa—St. Petersburg—Clearwater, FL.

⁷ Indexes on a November 1996 = 100 base.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date. Dash indicates data not available.

40. Annual data: Consumer Price Index, U.S. city average, all items and major groups

Dash indicates data are not available. Quarterly figures for France, Germany, Italy, and the Netherlands are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures. For further qualifications and historical annual data, see the BLS report *International Comparisons of Annual Labor Force Statistics, Adjusted to U.S. Concepts, 10 Countries* (on the internet at <http://www.bls.gov/lc/ilscmparelf.htm>).

For monthly unemployment rates, as well as the quarterly and annual rates published in this table, see the BLS report *International Unemployment Rates and Employment Indexes, Seasonally Adjusted* (on the internet at http://www.bls.gov/lc/intl_unemployment_rates_monthly.htm). Unemployment rates may differ between the two reports mentioned, because the former is updated annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.

52. Annual data: employment status of the working-age population, adjusted to U.S. concepts, 10 countries

¹ Data for 1989 and subsequent years are based on the *Standard Industrial Classification Manual*, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985–88, which were based on the *Standard Industrial Classification Manual*, 1972 Edition, 1977 Supplement.

² Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.

³ The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (NEH) X 200,000, where:

N = number of injuries and illnesses or lost workdays;
EH = total hours worked by all employees during the calendar year; and
200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year).

⁴ Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.

⁵ Excludes farms with fewer than 11 employees since 1976.

NOTE: Dash indicates data not available.

55. Fatal occupational injuries by event or exposure, 1996-2005

Event or exposure ¹	1996-2000 (average)	2001-2005 (average) ²	2005 ³	
			Number	Percent
All events	6,094	5,704	5,734	100
Transportation incidents	2,608	2,451	2,493	43
Highway	1,408	1,394	1,437	25
Collision between vehicles, mobile equipment	685	686	718	13
Moving in same direction	117	151	175	3
Moving in opposite directions, oncoming	247	254	265	5
Moving in intersection	151	137	134	2

Exposure to caustic, noxious, or allergenic substances	112	114	136	2
Oxygen deficiency	92	74	59	1
Fires and explosions	196	174	159	3
Fires--unintended or uncontrolled	103	95	93	2
Explosion	92	78	65	1

¹ Based on the 1992 BLS Occupational Injury and Illness Classification Manual.

² Excludes fatalities from the Sept. 11, 2001, terrorist attacks.

³ The BLS news release of August 10, 2006, reported a total of 5,702 fatal work injuries for calendar year 2005. Since then, an additional 32 job-related fatalities were identified, bringing the total job-related fatality count for 2005 to 5,734.

NOTE: Totals for all years are revised and final. Totals for major categories may include subcategories not shown separately. Dashes indicate no data reported or data that do not meet publication criteria. N.e.c. means "not elsewhere classified."
