REVIEW

U.S. Department of Labor

U.S. Bureau of Labor Statistics

Domestic employment in U.S.-based multinational companies

U.S. Department of Labor
Hilda L. Solis, Secretary

U.S. Bureau of Labor Statistics
Keith Hall, Commissioner

The *Monthly Labor Review* is published monthly by the Bureau of Labor Statistics of the U.S. Department of Labor. The *Review* welcomes articles on employment and unemployment, compensation and working conditions, the labor force, labor-management relations, productivity and technology, occupational safety and health, demographic trends, and other economic developments.

The *Review's* audience includes economists, statisticians, labor relations practitioners (lawyers, arbitrators, etc.), sociologists, and other professionals concerned with labor-related issues. Because the *Review* presents topics in labor economics in less forbidding formats than some social science journals, its audience also includes laypersons who are interested in the topics, but are not professionally trained economists, statisticians, and so forth.

In writing articles for the *Review*, authors should aim at the generalists in the audience on the assumption that the specialist will understand. Authors should use the simplest exposition of the subject consonant with accuracy and adherence to scientific methods of data collection, analysis, and drawings of conclusions. Papers should be factual and analytical, not polemical in tone. Potential articles, as well as communications on editorial matters, should be submitted to:

The October Review

In today's global economy, the prevalence of multinational companies located in the United States should come as no surprise. What may be of surprise, however, is that these often overlooked establishments employ millions of U.S. workers across the country and in a variety of industries and occupations. In this issue's lead article, BLS authors Elizabeth Weber Handwerker, Mina M. Kim, and Lowell Mason present details on the employment, wages, and geographic and occupational distributions of U.S.-based multinational manufacturing establishments. The findings, coming out of a joint BEA-BLS research project, indicate that these manufacturing establishments are located primarily in the South, employ a disproportionate number of engineers, and pay higher wages, on average, than other U.S. establishments. The authors state that the uncertainty as to why U.S.-based multinational manufacturing establishments pay higher wages is not known, but that further research could help explain this difference, and other differences, between domestic and multinational firms.

In our Regional Reports department, Rachel S. Friedman, formerly an economist in the Bureau's New York Regional Office for Economic Analysis and Information, analyzes the labor market effects of the real estate boom and bust on New York City from 2000 to 2010. The study uses employment data from the Bureau's Quarterly Census of Employment and Wages (QCEW) program to show that the construction boom that started in 2000 occurred in New York City later, but with *more* inten-

sity, than in the Nation as a whole. The eventual construction bust also occurred later in the City than nationally, but was, interestingly, relatively *less* severe.

The October issue concludes with another installment from our Regional Reports department. Lisa Boily, an economist in the Bureau's New York regional office, uses QCEW data to examine differences in pay—or pay premiums—between workers in New York City and the Nation's workers. The report indicates that workers in the City continued to earn more, on average, than workers in lower cost areas but that most of the increase in the City's pay premium from 1990 to 2009 is attributable to growth in average pay in the financial activities industries.

Injuries and illnesses, 2010

Nearly 3.1 million nonfatal workplace injuries and illnesses were reported among workers in private industry in 2010, resulting in an incidence rate of 3.5 cases per 100 equivalent full-time workers—down from 3.6 cases in 2009. However, the incidence rates for cases with days away from work; for cases of job transfer and restriction; and for cases of days away from work, job transfer, or restriction each remained unchanged from 2009.

Among the goods-producing industry sectors, incidence rates during 2010 ranged from 2.3 cases per 100 full-time workers in mining to 4.4 cases per 100 full-time workers in manufacturing. Within the service-providing industry sectors, incidence rates ranged from 0.8 case per 100 full-time workers in the finance and insurance sector to 5.2 cases per 100 full-time workers both

in the transportation and warehousing sector and in the health care and social assistance sector. The news release regarding these data is available at www.bls.gov/news.release/archives/osh_10202011.htm. Additional information is available from the Injuries, Illnesses, and Fatalities program at www.bls.gov/iif/home.htm.

Usual weekly earnings

Median weekly earnings of the Nation's 101.4 million full-time wage and salary workers were \$753 in the third quarter of 2011. This figure was 1.8 percent higher than a year earlier, compared with a gain of 3.8 percent in the Consumer Price Index for All Urban Consumers (CPI-U) over the same period.

The female-to-male earnings ratio varied by race and ethnicity. White women earned 82.5 percent as much as their male counterparts, compared with Black (90.2 percent), Asian (70.1 percent), and Hispanic women (92.9 percent). Among the major race and ethnicity groups, Black men working at full-time jobs had median weekly earnings of \$661 per week, or 78.0 percent of the median for white men (\$847). The difference was less among women: Black women's median earnings (\$596) were 85.3 percent of those for white women (\$699). Overall, median earnings of Hispanics who worked full time (\$545) were lower than those of Blacks (\$616), Whites (\$772), and Asians (\$869). The news release regarding these data is available at www.bls.gov/news.release/archives/wkyeng_10202011.htm. Additional information is available from the Current Population Survey at www.bls.gov/cps. □

Domestic employment in U.S.-based multinational companies

Establishments of multinational manufacturing firms in the United States are larger, are located disproportionately in the South, employ a disproportionate number of engineers, and pay higher wages, on average, than other U.S. establishments; these findings hold even after controlling for establishment industry, size, and age, and the interaction between industry and size

Elizabeth Weber
Handwerker,
Mina M. Kim,
and
Lowell Mason

The Bureau of Economic Analysis (BEA) collects data on multinational companies based in the United States—firms that have full or partial ownership of affiliate companies in foreign countries. However, BEA data offer little detail on the characteristics of these firms' U.S. employment. Identifying such firms in BLS data can show the geographic, occupation, and wage distributions of their employees in the United States. The popular media sometimes describe U.S. companies that make investments in companies overseas as “exporting good jobs,” but there is little evidence on the *domestic* employment characteristics of these firms, either before or after their overseas investments have taken place.

Typically, firms that own at least a 10-percent interest in a foreign company are described as being engaged in *foreign direct investment*.¹ In the economics literature, such companies have been shown to be systematically different from firms that focus on the domestic market.² In particular, firms with foreign affiliates tend to be larger and more productive than firms that have no foreign affiliates, but that sell their products internationally.³ Exporting firms in turn tend to be larger and more productive than firms that sell their products only on the domestic market.⁴ However, aside from establishing that the firms engaged in foreign direct investment tend to be large employers that pay higher wages, the literature has uncovered very little about the geographic, occupation, or wage distributions of employment

by U.S.-based multinational companies.

The research presented in this article is based on a joint BEA-BLS project that linked BEA firm-level data on U.S. multinational companies with BLS establishment-level data for all U.S. employers. By identifying a subset of all domestically located establishments in the BLS data that are the establishments of U.S.-based multinational companies, the article presents, for the first time, details on the employment, wages, and geographical and occupational distributions of these companies.

Background

Beginning with the enactment of the Foreign Direct Investment and International Financial Data Improvements Act of 1990, BLS and BEA collaborated to combine BEA data on foreign-owned businesses with BLS employment data until the funds dedicated to the project were eliminated. That project, which focused on the composition of domestic employment related to direct investments in the United States by foreign firms, produced the tabulations “Employment and Wages in Foreign-Owned Businesses in the United States” for 1989 through 1992 and “Occupations in Foreign-Owned Manufacturing Establishments in the United States” for 1989. Nowadays, there is more concern—reflected in both the popular press and the economic literature—about the impact of U.S. direct investment overseas on domestic employment.

Elizabeth Weber Handwerker is a research economist in the Office of Employment and Unemployment Statistics, Bureau of Labor Statistics, and Lowell Mason is an economist in the same office. Mina M. Kim is a research economist in the Office of Prices and Living Conditions. Email: handwerker.elizabeth.weber@bls.gov

From 2005 to 2007, a National Academy of Public Administration panel, authorized and funded by Congress, studied the definition, available data, and impact of offshoring on the U.S. economy. The panel produced three reports,⁵ and its efforts led to a memorandum of understanding between BEA and BLS. The memorandum permits relevant data sharing between the two agencies to investigate possible avenues for improving statistics through linking their data. The panel recommended that BEA and BLS work to link the BEA firm-level data on U.S. multinational companies with BLS establishment-level data for all U.S. employers. Following this recommendation, a team of researchers at BLS and BEA has been investigating the feasibility of linking the two datasets since the panel concluded its work in 2007.

Data and methods

In what follows, BEA data were used to match a pilot group of U.S. parent firms of multinational companies with their establishments appearing in BLS data. The pilot group consists of the largest 500 U.S.-based multinational manufacturers (by primary industry of the U.S. parent) in the BEA's firm-level data from the 2004 Benchmark Survey of U.S. Direct Investment Abroad. The efforts at matching were based primarily on the names, locations, and employer identification numbers (EINS)⁶ provided in this survey.

The BLS Quarterly Census of Employment and Wages (QCEW) is the starting point for identifying the establishments of firms in the pilot group for the years 2004 and 2005. The QCEW collects information on total employment by month and total wage bills (total wages paid by establishments) by quarter for all U.S. establishments covered in the Unemployment Insurance program, as well as detailed information on the industry of main activity (at the six-digit North American Industry Classification System (NAICS) level) and geographic location (at the Census block level) for each establishment.

These establishments were then matched with those sampled in the BLS Occupational Employment Statistics (OES) survey from November 2003 to May 2006. This survey collects data from a sample of 1.2 million establishments over each 3-year cycle. Sampled establishments provide data on the distribution of their employees' occupations (by the 801 detailed civilian occupations of the Standard Occupational Classification (SOC) system) and hourly wages (in 12 broad wage bands). To calculate average wages in the OES data, each employee is assigned a wage based on the mean wage for these wage bands, following the methods used in OES publications.⁷

The automatic matching efforts entail matching EINS between BEA firm-level data and BLS establishment-level data. BEA firm-level data contain only one or two EINS per firm, while BLS establishment-level data contain one EIN per establishment, and the establishments of each firm may report many different EINS in the BLS data. Thus, additional EINS for each firm are found by matching firm names and addresses with the establishment names and addresses in the QCEW, as well as by using company family lists (lists of employers that operate under different names but are part of the same company) from other BLS programs, company information in the Compustat database, and other sources of data on firms. However, such automated matching procedures are imperfect: some firms are matched with unrelated establishments, while other firms appear to be matched with only a fraction of their establishments in the QCEW. Accordingly, the lists of all establishments found through automated matching were reviewed manually, and the establishments matched in error were removed. Then, the QCEW was searched for additional establishments identified from company Web sites, filings from the Securities and Exchange Commission (SEC), and company annual reports.

On the advice of BEA staff, the firms identified in their surveys were considered to be "adequately matched" with BLS establishment data if the total employment of all matched BLS establishments for a particular firm was within 20 percent of the total employment reported in the BEA survey. Of the 500 firms in the pilot group, 201 were considered to be adequately matched with the QCEW data with the use of only automated matching methods. After several months of labor-intensive review and "hand matching," 453 of the 500 firms were believed to be adequately matched. The remainder of this article discusses results for these 453 firms, which employ 90 percent of the workers of the largest 500 manufacturers, as the following tabulation shows:

<i>Source of data and category of employment</i>	<i>Number of workers</i>
BEA data from 2004 Benchmark Survey of U.S. Direct Investment Abroad:	
Total domestic employment of companies in survey.....	22,445,900
Employment in these companies whose primary industry is manufacturing.....	7,628,500
Employment in the largest 500 of these companies.....	6,829,300
Employment in the 453 matched companies....	6,444,300
BLS data from QCEW and OES survey:	
Total employment in establishments matching with these 453 matched companies, per QCEW.....	6,112,919
Weighted ⁸ employment in establishments matching with these 453 matched companies, per OES survey.....	5,638,849

The establishments of the 453 adequately matched firms were then linked with establishments in the OES survey data. Because the OES sample design always includes all large establishments over the 3-year panel, about one-fifth of the matched establishments are part of the OES sample and responded to the survey between November 2003 and May 2006.

Caveats

Although a large portion of U.S. employment of U.S.-based multinational manufacturing companies was found in the QCEW and OES data, the missing employment is not random. The 453 multinational companies that were found to match with the BLS establishment data are different from the 47 firms that remained unmatched. For example, it was more difficult to match privately owned firms (which generally disclose less information than publicly owned firms and, in particular, do not file annual reports with the SEC) and firms that have undergone liquidation or reorganization since the survey date.

Even the establishments found in the 453 matched firms were not randomly distributed among those firms in ways that might affect the resulting estimates of wages and occupations. For example, in a multinational firm, 90 percent of whose BEA-estimated employment was found in the QCEW, matched establishments in the BLS data might include all of the firm's major manufacturing plants and just a few of the firm's smaller sales offices.

Furthermore, the sample design of the OES survey is intended to produce estimates at the State and industry levels, not to provide estimates for the unusual subsample of multinational firms examined in this article. The OES survey collects information from a sample of establishments rotating in 3-year panels, with sample probabilities that vary by establishment size. The probability that a larger establishment is included in the OES sample over the course of 3 years is greater than the probability that a small establishment is included. This difference could affect the distribution of occupations and wages in the subsample of establishments that are matched with multinational firms. In the extreme case, the distribution of occupations found in the OES data for a particular firm might represent only the large manufacturing plants of that firm, excluding the firm's sales and headquarters establishments. Consequently, the sample and nonsample variance of these estimates may be large.

Another concern is the difference in wage reporting between the QCEW and the OES survey. Total wage bills

in the QCEW data include bonuses and overtime pay for all employees on the payroll of an establishment for each quarter, whereas wage payments in the OES include only base hourly or annual wages for employees at the time the establishment is contacted by the survey. It was found that, among the establishments in the pilot group, those included in the OES survey reported monthly wage bills per employee in the QCEW data that were about 219 times the average hourly wages per employee they reported to the OES survey (approximately equivalent to 27 days' wages times 8 hours per day), while the typical ratio for all establishments was an average monthly wage bill per employee in the QCEW data that was about 135 times the average hourly wage per employee reported to the OES survey. The following tabulation gives the breakdown:

<i>Category of establishment</i>	<i>Average monthly QCEW wage bill</i>	<i>Average OES wages per hour</i>	<i>Ratio</i>
All U.S. establishments.....	\$2,538.53	\$18.84	135
Matched establishments.....	5,193.16	23.74	219

This different relationship between QCEW and OES wage data for U.S.-based multinational manufacturers, compared with typical U.S. employers, could be due to differences in average hours worked, particularly in the incidence of part-time employment, overtime pay, or bonuses. To reduce the impact of bonuses on the comparisons of multinational companies with other employers, QCEW data from the third quarter of 2004 were used instead of data from the fourth quarter, during which bonuses typically are largest. However, it is still possible that the multinational companies pay higher bonuses, even in the third quarter. It is also possible that some of the difference between the measurement of wages in the QCEW and OES data is due to underreporting and topcoding of wages in the OES for highly paid workers.

Results

Employment in the 453 matched companies among the 500 largest multinational manufacturers accounts for 4.7 percent of total U.S. employment measured in the QCEW. As one would expect from a matching effort that began with firms whose primary industry is manufacturing, most establishments of those firms are involved in manufacturing; about 67 percent of the firms' employment is in manufacturing establishments.

Table 1 compares employment and monthly wage bills (based on the QCEW for the third quarter of 2004) per employee, by industry (major sectors and subsectors), for

Table 1. Employment and wages for major industry groups and manufacturing subsectors, all United States and matched U.S. multinational manufacturing companies, third quarter, 2004

all U.S. establishments and for the establishments of the matched multinational manufacturing companies. In general, the establishments of these matched multinational manufacturers have higher employment per establishment than do all employers. This difference is particularly large in certain manufacturing subsectors, such as printing and textiles. The establishments of these matched multinational manufacturing companies also have higher wage bills per employee than all employers have. Later, regression analysis is used to decompose how much of the difference in wages shown in table 1 can be attributed to differences in the geographic composition, industries, sizes, and occupational distribution of workers in those establishments.

These findings echo those of Mark Doms and J. Bradford Jensen, who reported that U.S. multinational companies were larger and paid higher wages in 1987, on average, than either small or large domestically oriented firms or than foreign-owned firms.⁹ Controlling for establishment size, industry, age of the plant, and State in which the company is located, Doms and Jensen found that production workers in establishments of U.S. multinational companies were paid 7 percent more than those in establishments of large domestically oriented firms, about 17 percent more than those in establishments of small domestically oriented firms, and about 3 percent more than those in establishments of foreign-owned plants. These same authors found smaller differences in pay for nonproduction workers.

However, some of the differences in wages between all U.S. establishments and establishments of the matching multinational manufacturing companies are likely due to differences in the subsectors of the major industries in which the establishments are engaged. For example, the 142,085 U.S. establishments in educational services are largely public school establishments, whereas the 448 educational services establishments of multinational manufacturing companies are not.

Table 2 compares employment (based on the QCEW for the third quarter of 2004) by census region and division between all U.S. establishments and establishments of matched multinational manufacturing firms. The concentration of multinational employment ranges from 3.5 percent of employment in the West to 6.5 percent in the Midwest. More specifically, the concentration of multinational employment for the pilot group is greatest in the East North Central census division, where the companies in the group employ 6.9 percent of all workers. This census division also has the largest difference in employment between multinational employers and all employers: es-

tablishments of multinational employers average more than 5 times the size of average employers in the division. The difference in wage bills between matched multinational employers and all employers is greatest in the West, where the average matched multinational employer pays monthly wage bills per employee that are 2.3 times the monthly wage bills per employee of average employers overall.

Because the establishments examined in this article are in multinational *manufacturing* firms, some of the geographic distribution of matched establishments will be driven by the geographic distribution of the manufacturing industry throughout the United States. Table 2 shows that the manufacturing establishments—matched or not—are located mostly in the South and Midwest regions. Within manufacturing establishments, the fraction of employment that is in matched multinational employers ranges from 22.0 percent in the Middle Atlantic census division to 32.3 percent in the West South Central census division.

An interesting question that arises is, How is the geographic concentration of the matching multinational employers in the South and the Midwest regions influenced by factors such as industry composition? To answer this question, a simple linear probability regression may be performed for each geographic region. The regression results explain how much of the difference in the geographic locations of multinational employers is due only to differences in the industry composition, size classes, and ages of their establishments. For example, if large, older manufacturing plants are located predominantly in the Midwest and the matched multinational companies are composed disproportionately of large, older manufacturing establishments, this set of circumstances would explain the location of the matched multinational companies in the Midwest. The regressions take the form

$$y_i = \alpha + \beta \text{Match}_i + \gamma X_i + \varepsilon_i,$$

where y_i is the outcome variable of interest for establishment i (here, an indicator variable for the geographic region in which the establishment is located); Match_i is an indicator variable for whether establishment i matches with the multinational manufacturing parent firms identified in the BEA data; and X_i is a vector of establishment-level control variables (here, the industry,¹⁰ size class, interaction of industry with size class, and age¹¹ in the QCEW in the third quarter of 2004).

The results of these regressions are given in Table 3. The first column of numbers shows the coefficients (and

facturing companies in the pilot group. Thus, the coefficients on Match_{*i*} are biased toward zero. Furthermore, the incompleteness of the matching is not random, both because certain kinds of establishments are missing from the firms that were matched and because it was more difficult to match certain kinds of firms. As a result, given that the locations of the missing matched establishments are not known, neither is the direction of the resulting bias in the regression coefficients known, and the reported standard errors for these coefficients understate the true uncertainty of the estimates.

After adjustment for establishment size class, industry, and age, and for the interaction of industry with size class, the matched establishments turn out to be less likely than other establishments to be located in the Midwest, but they are still disproportionately located in the South, not in the Northeast or the West.

Table 4 shows the distribution of occupations in the OES data collected in the survey's six panels from November 2003 to May 2006, within the establishments of the matched multinational manufacturers. Because the OES data come from a sample, the weights from the OES (which account for sampling probabilities, among other factors) are used to weight the entries in the table.

These establishments employ a particularly high fraction of their employees in the production occupations group, which consists of supervisors of production workers (SOC 51-1000); assemblers and fabricators (51-2000); food processing workers (51-3000); metal workers and plastic workers (51-4000); printing workers (51-5000); textile, apparel, and furnishings workers (51-6000); woodworkers (51-7000); plant and system operators (51-8000); and other production occupations (51-9000). Matched estab-

lishments employ 33.1 percent of their workers in this occupational group, while all U.S. establishments collectively employ 7.7 percent of their employees in the group.

Matched establishments also employ a higher fraction of their employees than do all U.S. establishments in the following SOC groups: management (SOC 11); business and financial (13); computer and mathematical (15); architecture and engineering (17); life, physical, and social science (19); installation, maintenance, and repair (49); and transportation and material moving occupations (53). They employ a lower fraction of their employees in other groups: education, training, and library (25); healthcare practitioner and technical (29); healthcare support (31); protective service (33); food preparation and serving (SOC 35); building and grounds cleaning and maintenance (37); personal care and service (39); sales and related (41); office and administrative support (43); and construction and extraction occupations (47).

Much of this difference in occupational distribution derives from differences in the business activities of these establishments. Matched establishments are concentrated in manufacturing industries, which disproportionately employ people in the engineering and production occupations. Indeed, within the manufacturing establishments that can be matched with the U.S.-based multinational manufacturing firms, nearly 48 percent of all employees are in production occupations and more than 10 percent are in architecture and engineering occupations.

To see how much of the difference in occupations between employees in establishments of U.S.-based multinational manufacturing firms and those in other establishments stems from differences in the industries, sizes, locations, and ages of their employing establishments, simple linear probability regressions were conducted. These regressions are of the same form as the regressions used earlier, in which the outcome variable y_i is an indicator variable for each occupation.

As in table 3, the first column of numbers in table 5 shows the coefficients (and their standard errors) for the Match indicator without any controls X_i while the second column of numbers shows the coefficients (and their standard errors) for the Match indicator when controls for establishment industry, size class, age, and region, and for the interaction of industry with size class, are added. The variable of interest in these regressions is the occupational classification of the employees, so the regressions are weighted by the number of employees in each establishment, as well as the final benchmark weights from the OES. Again, the standard errors calculated for these regressions understate the true standard errors because

the matching is incomplete and the incompleteness is not random.

After controls are added for establishment industry, size class, age, and region, and for the interaction of industry with size class, the largest multinational manufacturers remain somewhat more likely to employ workers in the architecture and engineering; computer and mathematical; and installation, maintenance, and repair occupations. However, production workers are *less* likely to be employed in these matched establishments. These findings are consistent with the notion that multinational manufacturing employers have shifted some of their less skilled production work to plants overseas while retaining more skilled work in the United States. The findings are also consistent with the hypothesis that more productive firms with more highly skilled employees are more likely to become multinational firms.

The difference in wages between U.S.-based multinational manufacturers and other employers is examined with the use of similar controls. The following tabulation shows the

results of regressions using various control variables X_i to examine the impact on wages of matching to the BEA firm data (all coefficients β are significant at $p < .0001$):

Category	β	Standard error of β
Raw wage difference.....	\$2,690.50	(38.36)
Regression adjusted for—		
Census region.....	2,697.76	(38.36)
Size class of establishment.....	2,597.10	(38.36)
Age of establishment.....	2,455.55	(27.02)
Industry group.....	2,099.36	(38.88)
Specific industry.....	1,916.71	(39.69)
All control variables.....	1,673.41	(28.15)

In these regressions, the outcome variable y_i is the monthly wage bill per employee for all establishments. The first row of numbers shows the coefficient for the Match indicator without any controls X_i : U.S. parent firms of multinational manufacturers pay monthly wage bills per employee that are \$2,690.50 per month higher than those paid by other establishments.

Successive rows of numbers show that controlling for region has a negligible impact on this wage difference, whereas controlling instead for establishment size class, age, and industry has a more substantial effect. Controlling for the industry groups shown in table 1 reduces the wage difference to \$2,099.36, whereas controlling instead for specific six-digit NAICS industry categories reduces the wage difference even further, to \$1,916.71. Adjusting for all controls X_i (as well as for the interaction between industry groups and establishment size class) shows a monthly wage bill per employee that is \$1,673.41 higher in the establishments of U.S. parent firms of multinational manufacturers.

These estimates from regressions of establishment-level data show the differences in monthly wage bills per employee between establishments that belong to multinational manufacturing companies and other establishments. However, some establishments have more workers than other establishments, so the difference between average wages at matched and unmatched employers is not the same as the difference between average wages received by employees of matched and unmatched employers. Accordingly, to calculate the difference in monthly wage bills per employee between employees of establishments that belong to multinational manufacturing companies and employees of other establishments, the same regressions are performed, with the establishments weighted by their employment.

As shown in table 6, the average employee of a multinational manufacturer is paid a monthly wage bill that is \$2,290.59 higher than the employees of other employ-

ers. After establishment characteristics (region, size class, age, specific industry, and industry group interacted with size class) are controlled for, this wage premium falls to \$1,071.41 per month, smaller than the coefficient found in the unweighted regression. The difference in coefficients between the weighted and unweighted regressions suggests that the difference in wages between matched and unmatched establishments is greater in establishments with fewer employees.

The OES data also can be used in wage regressions. Here, y_i is the hourly wage level for each (weighted) employee. Regressions on the OES data show that the U.S. parent firms of multinational manufacturers pay hourly wages that are \$5.11 higher than those of other employers. (See table 6.) However, after controls are added for establishment region, size class, age, and specific industry, and for the interaction between industry group and size class, the difference falls to \$1.57, and after further controls are added for workers' occupations, the difference falls to \$1.20.

To compare the results obtained here with those of Doms and Jensen, regressions of the logarithm of wages were run separately for production and nonproduction workers. (For the comparison, production workers were defined as those employed in the major occupational categories 33, 37, 43, 47, 49, 51, and 53 in the weighted OES

data.) With establishment age, specific industry, and census division controlled for, the wage premium for production workers in the establishments of multinational manufacturers compared with that for production workers in other large establishments is nearly 5 percent and in other small establishments is about 13 percent. Analogous wage premiums are smaller for nonproduction workers in the establishments of multinational manufacturers. These estimates are similar to, but somewhat smaller than, the wage differences documented by Doms and Jensen between multinational and domestic manufacturing firms in 1987.

Even with establishment characteristics and workers' occupations controlled for, the results presented here show that the establishments matched with large multinational manufacturing firms pay their employees higher wages than do other establishments in the United States. However, the question remains, *Why* do the establishments of these firms pay higher wages? In one study, Raymond Mataloni found that U.S. establishments of large multinational manufacturing firms have higher levels of labor productivity than other U.S. establishments have.¹² It is also possible that these multinational firms have the same global levels of labor productivity as other firms, but have systematically moved their lower skilled work—particularly their lower skilled production work—overseas, leaving higher skilled, more productive, and more highly paid work in the United States.

Future work

The research presented here has combined firm identifiers from the BEA 2004 Benchmark Survey of U.S. Direct Investment Abroad with BLS microdata on employment in establishments of these firms, for a pilot group of the largest U.S.-based multinational manufacturing companies. Other information collected in the BEA survey, such as the magnitude or the destination countries of these companies' foreign investments, has not yet been used. This information would facilitate an examination, for example, of whether there are differences in the occupational distribution of U.S. employees between multinational manufacturing firms with investments overseas in high-wage countries and those with investments overseas in low-wage countries. BLS and BEA researchers are working to combine the BLS

Table 6. Difference in wage premium between matched and unmatched establishments¹

microdata collected in the OES Survey with the data items collected in the BEA Survey of U.S. Direct Investment Abroad.

Recent economic literature on international trade has emphasized the importance of heterogeneity among multinational firms in understanding how those firms structure their international operations.¹³ Stephen Yeaple, for example, shows that multinational firms tend to be more productive than other firms and multinational firms that are more productive own affiliates in a larger number of countries.¹⁴ In combining BLS establishment-level data with BEA firm-level data on the domestic and foreign

operations of these firms, it will be possible to examine how the activities of multinational manufacturers correspond to their employment structure in the United States. The activities measured by BEA include the magnitude and scope of foreign direct investment, the amount of intrafirm trade, the destination countries for foreign direct investment, the companies' degree of "global engagement," their trade in services, and so forth. The collaboration described here between BEA and BLS will enable researchers in both agencies to analyze the occupations and wage structures of U.S.-based multinational firms by the characteristics of their international activities. □

⁶ The Internal Revenue Service assigns the EIN, or Federal tax ID number, to identify a business entity. Most large companies with many establishments report more than one EIN to the BLS Quarterly Census of Employment and Wages. The one or two EINs that companies report to BEA in the Benchmark Survey of U.S. Direct Investment Abroad generally match only a fraction of these large companies' establishments.

⁷ The midpoints used for the wage bands in the OES survey are based on the exact distribution of wages in the National Compensation Survey. (For more information, see *Handbook of Methods* (U.S. Bureau of Labor Statistics, December 2008), chapter 3, "Occupational Employment Statistics," pp. 1–26, <http://www.bls.gov/opub/hom/pdf/homch3.pdf>, especially p. 16.)

⁸ In the OES survey, smaller establishments are sampled with lesser probability than larger establishments and are then given larger weights in calculating estimates.

⁹ Doms and Jensen, "Comparing Wages, Skills, and Productivity."

¹⁰ Using the same aggregation of industry groups as in table 1.

¹¹ The age of each establishment is the number of years that the establishment has been observed to have positive employment in the QCEW. Because the QCEW data are linked longitudinally back to the first quarter of 1990, an indicator variable is added for establishments which had positive employment at that time.

The construction boom and bust in New York City

During the construction boom that began in 2000, construction employment rose later and with more intensity in New York City than in the Nation as a whole, while the eventual construction bust was later but less severe in the City than nationally; the City's gains and losses were concentrated in Manhattan, Brooklyn, and Queens

Rachel S. Friedman

The real estate boom and bust of the 2000–2010 decade reshaped New York City's building landscape and, with it, the City's construction industry. During this decade, the City's construction industry first gained 12,980 jobs and then lost 20,803. While similar booms and busts occurred nationally, the rise and fall in New York City's construction employment differed from the Nation's in both length and timing.

Using employment data from the Bureau of Labor Statistics (BLS) Quarterly Census of Employment and Wages (QCEW),¹ this report provides a borough-wide analysis of the labor market effects of the real estate boom and bust on New York City from 2000 to 2010. In particular, the analysis focuses on how changes in the City's real estate market affected the local construction sector, and looks specifically at three subsectors: construction of buildings, heavy and civil engineering construction, and specialty trade contractors.²

Quarterly data from the QCEW program were chosen because they provided the most detailed picture of the construction industry and allowed for analysis of countywide contributions to changes in New York City's labor market.³ The mid-year of 2000 was selected as a starting

point because a number of observers believe that the boom got underway about that time.⁴ By using data that goes through mid-2010, this report analyzes New York City construction employment throughout a decade of change.⁵

The boom in New York City

From June 2000 through June 2006, the price of residential housing in the New York City area doubled.⁶ (See chart 1.) Throughout the period, prices rose, with one of the larger increases occurring in 2005. Driving this price increase in 2004 and later years were gains in employment and income in both the financial and legal services industries.⁷ Furthermore, low interest rates and wider availability of loans and mortgages also contributed to increased demand and concomitant higher prices for residential housing.

These higher prices triggered an expansion of the construction industry in New York City. While expenditures for new residential housing units rose during the early years of the decade, it is noteworthy that between June 2004 and June 2008, spending on new projects increased from \$211 million to \$1.5 billion.⁸ As a result, residential housing increased by 14,358 units in the City over the 4-year period.⁹

At the county level, the majority of the City's residential building activity was con-

Rachel S. Friedman was an economist in the Office for Economic Analysis and Information in the New York regional office of the Bureau of Labor Statistics when she wrote this report. She currently is a yield analyst at *The Wall Street Journal*. Email: rfriedman.bls@gmail.com.

Chart 1. S&P/Case-Shiller® home price indices, New York City and United States, 2000–2010

NOTE: Data for New York City are for June of each year; U.S. data are for the second quarter of each year.

concentrated in New York (known as the borough of Manhattan), Kings (Brooklyn), and Queens counties. From 2004 to 2008, these three counties showed large increases in spending (\$525 million, \$458 million, and \$300 million, respectively) and in newly-constructed units (5,448, 6,338, and 3,036). Richmond County (known as Staten Island) followed the trend but with smaller increases in spending and housing permits, while Bronx County exhibited declines in both measures of building activity over the 4-year period.

Although new residential building activity increased early in the decade, employment in New York City's construction industry fell for 3 years following the 2001 recession, dropping by 11,598, or 9.5 percent. However, beginning in 2004, employment in the City's construction industry rebounded. From June 2004 to June 2008, total employment in construction for all five counties rose by 20,071, or 18.3 percent. (See table 1.)

Within the sector, the specialty trade contractors subsector saw the largest increase over the 4-year period, adding 10,281 positions. Spurred by the expansion of the residential housing market, the construc-

tion of buildings subsector added 9,809 jobs between 2004 and 2008. Although this subsector had a smaller increase, it recorded a larger percent change (37.4 percent, compared to 13.6 percent for specialty trade). In comparison, the heavy and civil engineering construction subsector lost 19 jobs over the period.

At the county level, growth in the City's jobs for construction workers was largely concentrated in New York, Queens, and Kings Counties. New York County experienced the greatest spike in employment over the 4-year period, adding 8,200 positions.¹⁰ Two-thirds of Manhattan's new construction jobs were in the construction of buildings industry, while gains in specialty trade contractors accounted for the remaining third. Queens had the second largest numeric increase in employment, up 5,699. In both Queens and Kings Counties, job increases from 2004 to 2008 were concentrated in specialty trade contractors.

The national boom

Nationally, as in New York City, housing prices appreciated rapidly from 2000 through 2006, reflecting increases in demand. (See chart 1.) One difference between the United

States and New York City was that subprime loans were more prevalent in the Nation as a whole.¹¹

Stronger demand triggered, with a lag, increases in the supply of housing. Employment in the national construction industry dipped after the recession in 2001, but by 2003, when employment was at its lowest, it was only slightly below its level of 2000. Beginning in 2003, a year prior to the rebound in employment in New York City, national employment increased by 14.9 percent, peaking in 2006. (See chart 2.)

As was the case in New York City, specialty trade contractors accounted for the largest share of the additional jobs, but unlike New York, heavy and civil engineering also experienced substantial job growth. Despite this difference, employment in New York City's construction industry increased by a larger percentage (18.3 percent) over a longer period (2004 through 2008).

The national boom also was different from the City's boom with respect to the relationship between housing prices and construction employment. While national employment peaked with housing prices (as measured by the S&P/Case-Shiller® Home Price Index), employment in New York City continued to rise for 2 years after prices

peaked before ultimately joining the national downward cycle.

The bust in New York City

In 2006, the real estate bubble burst, sending housing prices across the United States on a downward spiral. Although housing prices in New York City also fell after 2006, the decline in property values was more moderate. Between June 2006 and June 2008, housing prices depreciated by 9.8 percent in New York City, while nationally the decline was 17.9 percent.¹² (See chart 1.)

During this 2-year period, falling real estate prices and rising subprime mortgage delinquencies nationwide set into motion a series of events that included the implosion of financial giants such as Lehman Brothers and Bear Stearns, the government-aided rescue of AIG (American International Group, Inc.), and the contraction of global credit markets.¹³ (It is important to note the connection between the credit crunch, which is one aspect of this crisis, and the construction industry, whose health relies on the ability of homebuyers and businesses to access mortgages and various types of loans.) Together, declining

Chart 2. Indices of construction employment, New York City and United States, June, 2000–2010

NOTE: Employment data are from the Quarterly Census of Employment and Wages program. Data are for private industry only and exclude workers not covered by Unemployment Insurance or Unemployment Compensation for Federal Employees programs.
SOURCE: U.S. Bureau of Labor Statistics.

housing prices and diminished access to credit ended the construction boom in New York City in 2008.

From June 2008, when new construction projects were at their height, to June 2009, spending on new residential housing units in New York City dropped by 91 percent to \$136 million; the drop in new construction spending translated into 15,927 fewer housing starts in New York City in June 2009 compared with 2008. These were the lowest figures recorded over the 10-year period. The number of dollars spent on new housing increased only slightly over the next year, reaching \$174 million in June 2010, and only 1,487 new units received permits.

This citywide decline in spending and permits was largely concentrated in New York, Kings, and Queens Counties. New York and Kings experienced the largest drops in spending and new units with decreases of \$481 million and 5,178 units, and \$470 million and 6,736 units, respectively. Queens followed with declines of \$345 million and 3,644 units. Richmond County showed smaller decreases in spending and permits, while Bronx County experienced a moderate increase in both measures. Although spending in New York City increased slightly over the year, it continued to decline through 2010 in New York and Richmond.

The contraction of the construction industry resulted in a decrease in employment of 16.0 percent from June 2008 to June 2010. (See chart 2.) Of the 20,803 jobs lost, 16,141 (78 percent of the positions) were in the specialty trade contractors subsector. The building construction subsector recorded a smaller loss, 6,580 jobs. The heavy and civil engineering construction subsector was unaffected by the collapse of demand for residential housing, and it added 1,918 positions between 2008 and 2010.

A closer look at the counties shows that the largest declines were spread across New York, Queens, and Kings Counties. Combined, these three counties lost 17,621 positions from June 2008 to June 2010. In Queens and Kings Counties, specialty trade contractors accounted for most of the decline, but in New York County the majority

of the losses were shared equally by building construction and specialty trade contractors.

The national bust

In contrast to New York City where employment plunged immediately after peaking, decreases at the national level were more moderate during the first two years after employment peaked. However, from June 2008 to June 2010, the national rate of decline in construction employment outpaced the rate in the City (down 23.4 percent nationwide, compared with a 16.0 percent drop locally). Some observers have noted that the greater extent of subprime lending at the national level resulted in higher rates of foreclosure, which in turn further diminished the demand for new housing.¹⁴ The reduced demand for construction at the national level resulted in construction employment in 2010 being 18.1 percent below its level of 2000. By contrast, construction employment in New York City in June 2010 was 6.7 percent below its decade-earlier level.

WHILE THE RISE AND FALL OF HOUSING PRICES IN NEW YORK CITY matched the timing of the national boom and bust, New York City's construction industry lagged national employment trends during periods both of growth and decline. In addition, local employment experienced a longer expansion and a larger percentage increase. During the boom, most of the City's new residential housing was built in New York, Kings, and Queens Counties. Not surprisingly, a large portion of the construction jobs added during the boom and lost during the bust also was concentrated in these three counties. Although there were low levels of building activity and construction employment in 2010, history has shown that construction in New York City is a cyclical industry, indicating that the sector will undoubtedly rebound. However, when the next upturn will begin is yet to be determined. □

Notes

¹ The data are derived from summaries of employment of workers covered by State and Federal unemployment insurance legislation and provided by State Workforce Agencies.

² According to the NAICS manual, the construction of buildings subsector (NAICS 236), at times referred to in this report as building construction, comprises establishments primarily responsible for the construction of buildings. The work performed may include new work, additions, alterations, or maintenance and repairs. The heavy and civil engineering construction subsector (NAICS 237) comprises establishments whose primary activity is the construction of entire engineer-

ing projects (e.g., highways and dams), and specialty trade contractors, whose primary activity is the production of a specific component for such projects. The specialty trade contractors subsector (NAICS 238) comprises establishments whose primary activity is performing specific activities (e.g., pouring concrete, site preparation, plumbing, painting, and electrical work) involved in building construction or other activities that are similar for all types of construction but that are not responsible for the entire project.

³ While data from the Current Employment Statistics (CES) program are more current, they are not available for all three detailed

industries for New York City.

⁴ New York University's Furman Center for Real Estate and Urban Policy used 2000 as the starting point of the boom in New York City. See the Center's *State of New York City's Housing & Neighborhoods 2009*, at furmancenter.org/research/sonychan/2009-report (visited August 3, 2010). "House of cards," a special report on property in the May 31, 2003 issue of the *Economist*, noted a rapid surge in house prices after 2000 in the United States and many other countries. See <http://www.economist.com/node/1794873> (visited October 24, 2011). George A. Akerlof and Robert J. Shiller contend that the boom in housing prices in the United States began at some point in the late 1990s and was well underway by 2000. See Akerlof and Shiller, *Animal Spirits: How Human Psychology Drives the Economy, and Why it Matters for Global Capitalism* (Princeton University Press), 2009.

⁵ Data in this release are not seasonally adjusted; accordingly, over-the-year analysis is used throughout.

⁶ The S&P/Case-Shiller® Home Price Index for the New York City area was used as a measure of price inflation. The index for New York rose from 106.00 to 215.83 between June 2000 and June 2006. Home Price Index data can be found at www.standardandpoors.com/indices.

⁷ See "Causes and Consequences of New York City's Residential Building Boom" in the Furman Center's report, *State of New York City's Housing & Neighborhoods 2009*, furmancenter.org/research/sonychan/2009-report (visited August 3, 2010).

⁸ See the U.S. Census Bureau at <http://censtats.census.gov/bldg/bldgprmt.shtml> for all permit and spending data cited in this report. This figure is the projected cost of construction for new residential housing units and does not include continuing costs from previous

housing starts.

⁹ In this article, new residential housing is measured by the total number of residential housing permits issued by the City of New York. Data on non-residential construction spending and permits were not available for New York City.

¹⁰ While data from the Bureau's QCEW program showed that New York County exhibited the largest gains in employment over the period, James Parrot of the Fiscal Policy Institute suggests that there is significant underreporting in Queens County's housing construction industry. For further reading on this subject, see "The underground economy in the New York City Affordable Housing Construction Industry," *Fiscal Policy Institute*, April 17, 2007, http://www.fiscalspolicy.org/publications2007/FPI_AffordableHousingApril2007.pdf (visited October 7, 2010).

¹¹ The percentage of subprime mortgages given nationwide was double that for New York City. ¹⁴ One in every 144 U.S. housing units filed for foreclosure in the second quarter of 2010, compared with 1 in every 629 housing units in New York State. See Realty Trac, www.realtytrac.com (visited March 8, 2011).

Pay premiums among major industry groups in New York City

Although workers in New York City continue to earn substantially more on average than workers in lower-cost areas, most of the rise in New York City's pay premium is attributable to growth in average pay in the financial activities industries; despite a 2007–2009 decline, the financial activities pay premium nearly doubled during the 1990–2009 period

Lisa Boily

New York City's pay premium—the percent by which people who work in the combined five counties of New York City were paid above the national average—has risen substantially since 1990.¹ Employees in New York City earned an average of \$34,381 in 1990, which was 46 percent above the national average, and earned \$73,845 in 2009, 62 percent above the national average.² After adjustment for inflation, average annual earnings of New Yorkers rose 26 percent over the 19-year period, while the earnings of U.S. workers rose 18 percent. In the City's financial activities industries, the growth in pay premiums was even more pronounced, rising from 83 percent in 1990 to 163 percent in 2009, with average annual pay among employees in New York financial firms rising from \$52,227 to \$183,925 over the same period. (See table 1.)

Given the City's widely acknowledged high cost of living, it is no surprise that, on average, people who work in New York City earned more than those in the Nation as a whole, nor is it any surprise that the City's financial activities employees earned significantly more than the national average for employees in the financial activities supersector. What is less clear is how the vast majority of people—those who worked outside the financial activi-

ties supersector, which is defined by the Bureau of Labor Statistics (BLS) as the finance and insurance sector plus the real estate and rental and leasing sector—shared in the overall pay premium growth. This report uses data from the BLS Quarterly Census of Employment and Wages (QCEW)³ to shed light on how New York City's pay premium growth affected the pay of employees in both financial activities and non-financial activities. QCEW wage data are particularly well-suited for examining this relationship because they include cash payments, such as bonuses and profit distributions, as well as base wages and salaries. This comprehensive picture of total cash compensation is important when analyzing pay relationships in the financial activities supersector, where bonuses can represent a significant percentage of overall pay.

Because the QCEW produces county-level data, New York City data were generated by combining information for the city's component counties: Bronx, Kings (Brooklyn), New York (Manhattan), Queens, and Richmond (Staten Island). This report provides a close examination of employment and wages in New York City's five largest supersectors.⁴ For each of the supersectors examined, employment and wages in the City are compared with employment and wages in the supersector for the Nation as a whole. The resulting pay premium, therefore, is the New York City premium paid compared to

¹ Excludes workers not covered by Unemployment Insurance or Unemployment Compensation for Federal Employees programs.

² Includes non-wage cash payments such as bonuses, the cash value of meals and lodging when supplied, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as 401(k) plans and stock options.

³ The pay premium can be calculated in the following ways:

$$\frac{(\text{N.Y.C. share of U.S. total wages} - \text{N.Y.C. share of U.S. employment}) / \text{N.Y.C. share of U.S. employment}}{\times 100}$$

$$[(\text{N.Y.C. average wage} / \text{U.S. average wage}) \times 100] - 100$$

Pay premiums were calculated using unrounded data.

⁴ "Total except financial activities" includes the natural resources and mining supersector and the manufacturing supersector which are not shown separately because data are not available for these industries for Richmond County.

NOTE: Data for each of the BLS supersectors shown, except for government, are for private industry only.

SOURCE: U.S. Bureau of Labor Statistics, Quarterly Census of Employment and Wages.

the wages in the same supersector nationally.

The analysis begins with a focus on financial activities employment in the private sector. Then employment for all industries (both private and public sector) excluding the financial activities supersector is examined. (See table 1.) These non-financial industries accounted for 88 percent of New York City employment in 2009. Non-financial-activities employment is further subdivided into the following private-sector industries: education and health services; professional and business services; and trade, transportation, and utilities. Finally, the government supersector is examined. A brief discussion of real wage growth—that is, wages deflated by the Consumer Price Index—for both financial and non-financial industries over the 19-year period concludes the analysis.

Pay premiums by supersector

Financial activities. Throughout the period studied, the financial activities supersector was the single largest contributor to New York City's wage base. In 2009, this supersector alone accounted for 30 percent of the City's total wages. New York's financial supersector demonstrated great volatility in terms of its share of the Nation's financial activities wages, as demonstrated by chart 1. Cyclical changes included a rebound after the 1990–1991 recession, followed by a gradual build-up to the 2001 peak. Then the 2001 recession brought about a steep decline that was followed by a post-recession build-up beginning in 2003 and peaking in 2007. Finally, the effects of the most recent recession are clearly visible with the 2009 wage share decline. Nearly all of the upward movements in wage share during the 1990–2009 period were the result of increases in total wages in the financial activities supersector in New York City.

The financial activities supersector has followed the trend of the City's employment base as a whole by demonstrating, as also shown on chart 1, a gradual decline in its share of the Nation's employment. The percent difference between the supersector's relative wages and relative employment, which for the purposes of this report is called a pay premium, has also varied widely over this period. Reflecting this volatility, the premium was lowest in 1990 at 83 percent and highest in 2007 at 208 percent, clearly a substantial increase. Even considering the premium-dampening effects of the most recent recession, the City's financial activities supersector has benefited greatly from its steady hold

on its share of the Nation's financial activities wages, in spite of the fact that the City's overall employment share is in decline and the financial activities supersector itself has lost 16 percent of its employment since 1990. (See table 1.)

As noted earlier, most New York City employees work in supersectors other than financial activities. As shown in chart 2, New York City's share of the Nation's non-financial-activities wages and employment is much smaller than that of financial activities. Also, both employment and wage shares in the non-financial-activities industries were relatively flat over the 19-year period. Removing financial activities employment and wages from the equation, the City shows remarkable stability in its shares of both employment and wages over time, with employment shares declining only 0.3 percentage point and wage shares declining 0.4 percentage point between 1990 and 2009. Even so, there is a premium paid to the City's non-financial-activities employees. That premium also shows remarkable stability, remaining in a narrow band of 33-to-38 percent over the period studied.

From 1990 to 2009, employees who worked outside of financial activities saw a 1.0-percentage-point drop in their pay premium, compared to the overall growth of 16 percentage points for employees in all industries combined. That is, the 88 percent of City employees who worked outside the financial activities supersector did not benefit, on average, from the run-up of the City's pay premium over the period examined.

Education and health services. The consistency in pay premiums over time does not hold, however, when individual supersectors are evaluated. In contrast to financial activities, the education and health services supersector experienced a slight percentage decline in both employment share (down 0.5 percentage point) and wage share (down 0.7 percentage point) since 1990. This supersector has seen a 5-percentage-point drop in its pay premium since 1990, from 16 to 11 percent. Although employment growth within the education and health supersector was slower in New York City than in the Nation as a whole, education and health continued to account for an increasing share of employment in New York City, growing from 13 percent in 1990 to 20 percent in 2009. BLS projections indicate that healthcare nationally will generate 3.2 million new wage and salary jobs between 2008 and 2018, more than any other industry. Moreover, 10 of the 20 fastest-growing occupations are related to healthcare.⁵ Meanwhile, the education sector is projected to grow at a rate slightly above the average.⁶

Professional and business services. Professional and business services also lost both employment and wage shares, dropping by 1.2 percentage points and 1.6 percentage points, respec-

SOURCE: U.S. Bureau of Labor Statistics, Quarterly Census of Employment and Wages.

tively. However, unlike the education and health supersector, the pay premium in professional and business services increased 8 percentage points from 49 to 57 percent over the 19-year period as average professional and business services supersector wages rose faster in New York City than in the nation as a whole. Although this supersector, with its 8-percentage-point rise in pay premium, had an increase that was smaller than the average for the City as a whole, it was the only other supersector of the five given close examination in this report to experience any growth in its pay premium.

Trade, transportation, and utilities. The trade, transportation, and utilities supersector pay premium dropped by 15 percentage points since 1990, posting the greatest loss of the five major supersectors in New York City. In a pattern similar to that of education and health services, the wage share in this supersector dropped at a faster pace than the employment share. Unlike education and health services, the trade, transportation, and utilities supersector experienced a net loss in employment as its employment level declined 8 percent from 1990 to 2009.

Government. Government employment—Federal, State, and local—in New York City declined 7 percent over the

period studied, compared to an employment growth rate of 2.3 percent for all industries combined. The pay premium for government employees dropped from 29 percent in 1990 to 17 percent in 2009; government employment as a proportion of U.S. employment declined 0.8 percentage point and total government wages as a proportion of total U.S. wages dropped by 1.3 percentage points. Nationally, government employment is expected to grow at a slower pace than the all-industry average through the projection period which ends in 2018.⁷ Despite ongoing government employment declines in New York City, the government supersector was one of the City's largest supersectors and, in 2009, represented 15 percent of total New York City employment. These employees, on average, have seen a steady erosion of their pay advantage since 1990.

Real wages

In a pattern similar to the changes in its pay premium, New York City's financial activities supersector enjoyed a 166 percent increase in real wages from 1990 to 2007, and then lost 60 percentage points of that gain during the following two years, bringing the supersector's pay premium back to where it was around 2001. For the Nation as a whole, real wages in financial activities grew by 64 percent

Chart 3. Index of real wages for financial activities supersector, United States and New York City, 1990–2009 annual averages

NOTE: Data are for private industry only and exclude workers not covered by Unemployment Insurance or Unemployment Compensation for Federal Employees programs. Wages include non-wage cash payments such as bonuses, the cash value of meals and lodging when supplied, tips and other gratuities and, in some States, employer contributions to certain deferred compensation plans.

SOURCE: U.S. Bureau of Labor Statistics, Quarterly Census of Employment and Wages.

from 1990 to 2007 and then lost 14 percentage points from the 2007 peak to 2009.⁸ (See chart 3.) Meanwhile, real wage growth in the City's non-financial-activities sectors lagged that of the Nation; those rates were 10 percent and 15 percent, respectively. (See chart 4.)

THE PAY PREMIUM FOR FINANCIAL ACTIVITIES EMPLOYEES IN NEW YORK CITY INCREASED DRAMATICALLY during the 1990–2009 period, despite declines from 2007 to 2009. Furthermore, most recent data show that the supersector recovered some of its 2007–2009 losses in 2010. (The New York City premium was 178 percent in 2010, up 15 percentage points over the year, as

the City's annual financial activities pay rose to \$205,889, according to preliminary data.) Financial activities employment was the largest contributor to the City's pay premium growth over the 19-year period. In fact, among New York City's five largest supersectors, the pay of employees in three of them—trade, transportation, and utilities; education and health services; and government—actually lost ground since 1990, while the New York City professional and business services supersector experienced modest growth in its pay premium. When considered as a whole, at least 75 percent of New York City's non-financial-activities employment was located in supersectors where pay premiums remained relatively stable or declined. □

Chart 4. Index of real wages for all BLS supersectors except financial activities, United States and New York City, 1990–2009 annual averages

SOURCE: U.S. Bureau of Labor Statistics, Quarterly Census of Employment and Wages.

Notes

¹ Employment and pay data for New York City were calculated by summing published data from the Quarterly Census of Employment and Wages (QCEW) for Bronx, Kings, New York, Queens, and Richmond Counties for workers covered by Unemployment Insurance and Unemployment Compensation for Federal Employees programs.

The pay premium can be calculated in two ways, which both yield the same result. The pay premium expressed as the difference between payroll and employment shares is as follows:

$(\text{N.Y.C. share of U.S. total wages} - \text{N.Y.C. share of U.S. employment}) / (\text{N.Y.C. share of U.S. employment}) \times 100$.

Alternatively, because the average wage = total wages/employment, the pay premium expressed as a relationship between the City's and the Nation's average wages is as follows:

$[(\text{N.Y.C. average wage} / \text{U.S. average wage}) \times 100] - 100$.

² Included in average annual pay and total wages are non-wage cash payments such as bonuses, the cash value of meals and lodging when supplied, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as 401(k) plans and stock options.

³ The employment and wage data used in this summary were obtained from the Quarterly Census of Employment and Wages of the Bureau of Labor Statistics. All data presented here are for "covered employment"—that is, for workers covered by State and Federal un-

employment insurance programs. Annual average data were used to smooth out quarterly variations in payroll data.

⁴ The North American Industrial Classification System (NAICS) is based on grouping establishments into industries according to similarity in the processes used to produce goods or services. This analysis uses the BLS standard for aggregating industries into 11 supersectors: natural resources and mining; construction; manufacturing; trade, transportation, and utilities; information; financial activities; professional and business services; education and health services; leisure and hospitality; other services; and government.

⁵ *Career Guide to Industries*, 2010–11 Edition, <http://www.bls.gov/oco/cg/>.

⁶ *Ibid.*

⁷ *Ibid.*

⁸ In this report, the New York-Northern New Jersey-Long Island, NY-NJ-CT-PA, CPI-U was used to deflate New York City wages. This area is comprised of New York City, Dutchess, Nassau, Orange, Putnam, Rockland, Suffolk, and Westchester counties in New York State; Bergen, Essex, Hudson, Hunterdon, Mercer, Middlesex, Monmouth, Morris, Ocean, Passaic, Somerset, Sussex, and Union and Warren counties in New Jersey; Fairfield County and parts of Litchfield, Middlesex, and New Haven counties in Connecticut, and Pike County in Pennsylvania.

Keys to the City

One look at a city dweller's grocery bill makes it clear that nearly everything costs more in a metropolitan area. Because of this, wages are higher, too. Yet firms opt for city locations despite the relatively high labor costs. In fact, metro areas account for nearly 85 percent of the Nation's jobs, as well as almost 80 percent of the U.S. population. In his article "Three Keys to the City" (*Business Review*, Federal Reserve Bank of Philadelphia, third quarter 2011), economist Gerald Carlino explores why businesses continue to operate in cities when moving elsewhere could significantly lower operating costs.

Carlino analyzes the latest efforts to measure each of the sources of city productivity, which he calls the three "keys to the city"—resources, the economies of agglomeration, and sorting. He focuses his analysis on agglomeration economies, which are the benefits firms receive from locating near each other, and sorting; natural resources (such as the presence of a port or raw materials) continue to decrease in economic importance as transportation improves, technology progresses, and as more manufacturing jobs are replaced with jobs in service-related industries.

Historically, economists relied on agglomeration economies to explain how the high concentrations of people and jobs in cities led to efficiency gains and cost savings for firms. Businesses set up shop in emerging U.S. cities during the eighteenth and nineteenth centuries to be close to suppliers, workers, and customers. With advances in technology and transportation, proximity is no

longer required for success. However, Carlino stresses that agglomeration economies still help account for increased productivity: "If agglomeration economies are important, they will make workers in large cities more productive than workers in small cities and rural areas." The article focuses on two main types of agglomeration economies: business agglomeration economies, which increase the productivity of firms and workers, and consumer agglomeration economies, which improve the quality of leisure activities. Recent estimates of business and consumer agglomeration economies suggest that a doubling of city size increases productivity by about 3 to 4 percent.

Cities attract a disproportionate share of highly skilled workers. A talented, flexible workforce makes it easier for entrepreneurs to start new businesses and for existing businesses to find better matches for job openings. Carlino found that a skilled work force (as measured by the percent of the adult population with a college degree) was by far the most powerful determinant of innovative activity: a 10-percent increase in the proportion of the adult population that graduated from college is associated with an almost 9-percent increase in patents per capita. He suggests that highly skilled workers are better able to articulate and communicate ideas to others and to adapt to new technologies; together these lead to increased knowledge exchange among workers.

The author reasons that a city must be able to attract the best workers possible to ensure prosperity and growth. Cities do this by offering higher wages as well as more activities for its inhabitants. In Carlino's study, a doubling of the population

in a metropolitan statistical area led to a 3-to-6-percent increase in average wages. Characteristics that attract tourists—such as scenic views, architectural beauty, and cultural or recreational opportunities—are the same ones that attract workers to cities. In a study the author conducted in the 1990s, the 10-year population growth rate was 2.2 percentage points higher and the concomitant job growth was 2.6 percentage points higher in a city with twice the level of leisure tourists as another city. Carlino suggests, therefore, that consumer agglomeration economies can serve as an indicator of future growth for cities.

Effects of parents' education on child's schooling

It is well documented that the children of parents with more schooling tend to attain higher levels of education than children of parents with less education. The more difficult problem for researchers is establishing the *causal* relationship between the education levels of parents and their children. In other words, *why* do children of more educated parents end up with more education? The answer to this question has important policy implications because of the large role education plays in labor market outcomes. The issue also raises the ancient "nature versus nurture" question. Do parents with more education tend to have children with more ability to do well in school (nature)? Or do more educated parents have greater access to resources and possess attitudes and values that are supportive of higher educational attainment and therefore can provide their children with better environments in which to

study (nurture)? Empirical studies examining this issue have reached different conclusions.

In a recent article entitled “The Causal Effects of Parents’ Schooling on Children’s Schooling: A Comparison of Estimation Methods” published by the American Economic Association in its September 2011 issue of the *Journal of Economic Literature*, Helena Holmlund, Mikael Lindahl, and Erik Plug conduct a rigorous comparison of the various methods used by researchers in their attempts to solve this perplexing problem. The authors also try to explain why the existing studies have reached such different and often conflicting conclusions. They contend that explaining these differences is crucial to answering the question of why parents with more education tend to have children who attain higher levels of education. The study’s basic conclusion is that the differences can be attributed largely to varying methods of estimation, particularly in the areas of selection, “identification strategies,” and the assumptions underlying the studies’ models. A second and related factor that helps explain the different findings involves differences in the data used in the earlier studies.

Holmlund and her coauthors begin with a review of the existing literature, grouping the various studies into three categories based on three different identification strategies. The first approach deals with identical twins and differences in their educational levels. The second deals with adoptees and relies on the assumption that no genetic connection

exists between adoptees and their adoptive parents. The third identification strategy employs the method of instrumental variables (IV), a statistical technique used to estimate causal relationships when controlled experiments are not possible. The authors assemble, group, and critique the existing literature on intergenerational schooling effects as they attempt to explain the discrepancies in conclusions from one study to another. To test the efficacy of the methods used in the previous studies, they suggest applying all three identification strategies to one data set. The authors use Swedish administrative records because these data include the requisite information for each of the three strategies, which allows the authors to compare the different methods using data from the same country and the same cohorts.

The authors also look closely at the earlier studies’ estimation techniques, the specifications of their models and explanatory variables, and the selection of control variables used in their models. They find little variation in the estimation techniques—nearly all use some form of least squares and regression analysis—but they discover some interesting differences in the choice of control variables in the studies. In particular, the studies vary in whether to include a control variable for spousal education, a choice that can have substantial effects on outcomes. The authors assert that controlling for spousal education is important, for example, when the focus is on the intergenerational effects of increasing the

mothers’ education levels, but it is less important when the primary interest is in the children’s level of education. At this point, according to the authors, it remains unclear whether the mother’s schooling, the father’s schooling, or the combined schooling of both parents is the dominant factor determining the child’s own educational attainment. The evidence does, however, suggest that education itself is at least partly responsible for the intergenerational link—parents with more education get children with more education *because* the former have more education. That is, regardless of the economic benefits that are likely to accrue to parents with more schooling, parents tend to transfer education to their children.

Holmlund, Lindahl, and Plug find that, despite the methodological problems inherent in many of the tools and techniques used to establish the causal relationship between parents’ education levels and those of their children, the studies have been successful in the sense that they provide many new insights into the process by which parents transmit education to their children. Although some studies suggest that inherited abilities (nature) play the more substantial role in the educational link between parents and children, the available evidence shows that environmental factors (nurture) play an important part as well. Holmlund, Lindahl, and Plug suggest further research be conducted about causal relationships in order for positive changes to be made in future educational and labor market outcomes. □

Matching good people and good jobs

Where are All the Good Jobs Going? What National and Local Job Quality and Dynamics Mean for U.S. Workers. By Harry J. Holzer, Julia I. Lane, David B. Rosenblum and Frederik Andersson, New York, NY, Russell Sage Foundation, 2011, 222 pp., \$24.95/paperback.

In this book, the authors estimate trends in labor supply and demand over the 1992–2003 period for a sample of 12 states for which detailed firm and worker data are available. These data are drawn from the Census Bureau's Longitudinal Employer-Household Dynamics (LEHD) files, which uses state Unemployment Insurance quarterly reports on employees and employers melded with demographic information from Social Security records.

The resulting data set provides a very large sample of longitudinal data on workers and firms, allowing the authors to estimate person and firm "fixed effects" from which they can identify good workers and good jobs. The "worker-effect" measure represents the market value of the individual's skills and experience, while the "firm-effect" measure represents the extent to which the firm pays workers more or less than they would earn on average. Such premiums or discounts reflect productivity

differences, unionization, compensating differentials for unpleasant or dangerous work, and the training and human resource policies chosen by the firm.

When the authors cross-tabulate the quintiles of worker effects with the quintiles of firm effects, they discover that workers in a given firm-effect quintile are most likely to come from the same worker quintile. This "clustering" is most evident in the first and fifth quintiles. The percentages of given quintile workers in the same firm quintile are: 1-1, 66.8; 2-2, 37.4; 3-3, 34.5; 4-4, 40.1; 5-5, 61.2. This implies that the best-qualified workers and the least-qualified workers are more likely to be matched to jobs that fit their backgrounds than are workers in the middle three quintiles. About 23 to 27 percent of a given firm-quintile's workforce consists of workers from the next-higher or next-lower work effect quintile.

There are some important trends over the sample period. The ability of workers to find good jobs is increasingly correlated with their position in the distribution of worker effects and education. On an industry basis, manufacturing provides a smaller share of jobs in the top two quintiles of firm effects, while professional services, information, and other sectors for which post-secondary qualifications are typically required provide a larger share of these good jobs. As the authors put it, "More

broadly, we find a trend in which the quality of the jobs obtained by workers is more closely aligned with their personal skills..."

The authors use their data to analyze other dimensions of labor market behavior in policy-relevant ways. Among them are the impact of job changing (especially involuntary displacement) on the employment and earnings prospects of workers; differences in employment growth among larger and smaller metropolitan areas; and how net job creation is the result of firm births and deaths as well as employment growth by continuing firms. In particular, the analysis suggests that larger "high road" firms that attempt to hire better-qualified workers are the largest source of good jobs.

The authors conclude by outlining policy issues and programs that address enhancing workers' skills and encouraging the creation of more high-quality jobs. They are well aware of the financial and institutional constraints under which Federal, state and local agencies must operate, and their thoughts will be helpful to policy makers. In sum, this is a rich book in which four knowledgeable economists address labor market problems of increasing importance. I recommend it highly.

Book review interest?

Interested in reviewing a book for the *Monthly Labor Review*? We have a number of books by distinguished authors on economics, industrial relations, other social sciences, and related issues waiting to be reviewed. Please contact us via e-mail at mlr@bls.gov for more information.

Nominations Sought for 2012 Julius Shiskin Award

Nominations are invited for the annual Julius Shiskin Memorial Award for Economic Statistics. The Award is given in recognition of unusually original and important contributions in the development of economic statistics or in the use of statistics in interpreting the economy. Contributions are recognized for statistical research, development of statistical tools, application of information technology techniques, use of economic statistical programs, management of statistical programs, or developing public understanding of measurement issues. The Award was established in 1980 by the Washington Statistical Society (WSS) and is now cosponsored by the WSS, the National Association for Business Economics, and the Business and Economics Statistics Section of the American Statistical Association (ASA). The 2011 award recipient was Thomas L. Mesenbourg Jr., the Deputy Director of the U.S. Census Bureau, for his contributions to developing and advancing economic statistics programs that meet the needs of a rapidly changing economy.

The award is in memory of Julius Shiskin, who had a varied and remarkable public service career. At the time of his death in 1978, "Julie" was the Commissioner for the Bureau of Labor Statistics (BLS) and earlier served as the Chief Statistician at the Office of Management and Budget (OMB), and the Chief Economic Statistician and Assistant Director of the Census Bureau. Throughout his career, he was known as an innovator. At Census he was instrumental in developing an electronic computer method for seasonal adjustment. In 1961, he published *Signals of Recession and Recovery*, which laid the groundwork for the calculation of monthly economic indicators, and he developed the monthly Census report *Business Conditions Digest* to disseminate them to the public. In 1969, he was appointed Chief Statistician at OMB where he developed the policies and procedures that govern the release of key economic indicators (Statistical Policy Directive Number 3), and originated a Social Indicators report. In 1973, he was selected to head BLS where he was instrumental in preserving the integrity and independence of the BLS labor force data and directed the most comprehensive revision in the history of the Consumer Price Index (CPI), which included a new CPI for all urban consumers.

Nominations for the 2012 award are now being accepted. Individuals and groups in the public or private sector from any country can be nominated. The award will be presented with an honorarium of \$1000 plus additional recognition from the sponsors. A nomination form and a list of all previous recipients are available on the ASA Website at www.amstat.org/sections/bus_econ/shiskin.html.

For questions or more information, please contact Steven Paben, Julius Shiskin Award Committee Secretary, via e-mail at paben.steven@bls.gov or call 202-691-6147.

Completed nominations must be received by March 15, 2012.

55. Fatal occupational injuries by event or exposure 108

Notes on Current Labor Statistics

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as “seasonally adjusted.” (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables 1–14, 17–21, 48, and 52. Seasonally adjusted labor force data in tables 1 and 4–9 and seasonally adjusted establishment survey data shown in tables 1, 12–14, and 17 usually are revised in the March issue of the *Review*. A brief explanation of the seasonal adjustment methodology appears in “Notes on the data.”

Revisions in the productivity data in table 54 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All-Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the “real” earnings shown in table 14—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of \$3 and a current price index number of 150, where 1982 = 100, the hourly rate expressed in 1982 dollars is \$2 ($\$3/150 \times 100 = \2). The \$2 (or any other resulting

values) are described as “real,” “constant,” or “1982” dollars.

Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see *BLS Handbook of Methods*, Bulletin 2490. Users also may wish to consult *Major Programs of the Bureau of Labor Statistics*, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau’s monthly publication, *Employment and Earnings*. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:

www.bls.gov/cps/

Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:

www.bls.gov/ces/

Additional information on labor force data for areas below the national level are provided in the BLS annual report, *Geographic Profile of Employment and Unemployment*.

For a comprehensive discussion of the Employment Cost Index, see *Employment Cost Indexes and Levels, 1975–95*, BLS Bulletin 2466. The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: *Employee Benefits in Medium and Large Firms*; *Employee Benefits in Small Private Establishments*; and *Employee Benefits in State and Local Governments*.

More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report* and *Producer Price Indexes*. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the *Monthly Labor Review*. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

www.bls.gov/lpc/

For additional information on international comparisons data, see *International Comparisons of Unemployment*, Bulletin

1979.

Detailed data on the occupational injury and illness series are published in *Occupational Injuries and Illnesses in the United States, by Industry*, a BLS annual bulletin.

Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

n.e.c. = not elsewhere classified.

n.e.s. = not elsewhere specified.

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.

r = revised. Generally, this revision reflects the availability of later data, but also may reflect other adjustments.

Comparative Indicators

(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population (“household”) Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index

program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

Employment and Unemployment Data

(Tables 1; 4–29)

Household survey data

Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work

because they were on layoff are also counted among the unemployed. **The unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population. Persons **not in the labor force** are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The **civilian noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The **civilian labor force participation rate** is the proportion of the civilian noninstitutional population that is in the labor force. The **employment-population ratio** is employment as a percent of the civilian noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of *Employment and Earnings*. For a discussion of changes introduced in January 2003, see “Revisions to the Current Population Survey Effective in January 2003” in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at www.bls.gov/cps/rvcps03.pdf).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See “Revision of Seasonally Adjusted Labor Force Series in 2003,” in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at www.bls.gov/cps/cpsrs.pdf) for a discussion of the introduction of the use of X-12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the January–June period. The historical season-

ally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July–December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691–6378.

Establishment survey data

Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its co-operating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2007 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goods-producing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private service-providing industries, data are collected for nonsupervisory workers, which include most employees except those in executive, managerial, and supervisory posi-

tions. Those workers mentioned in tables 11–16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private service-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. **Overtime hours** represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The **Diffusion Index** represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

Notes on the data

With the release of data for January 2010, the CES program introduced its annual revision of national estimates of employment, hours, and earnings from the monthly survey of nonfarm establishments. Each year, the CES survey realigns its sample-based estimates to incorporate universe counts of employment—a process known as benchmarking. Comprehensive counts of employment, or benchmarks, are derived primarily from unemployment insurance (UI) tax reports that nearly all employers are required to file with State Workforce Agencies. With the release in June 2003, CES completed the transition from its original quota sample design to a

probability-based sample design. The industry-coding update included reconstruction of historical estimates in order to preserve time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the June 2003 issue of *Employment and Earnings* and “Recent changes in the national Current Employment Statistics survey,” *Monthly Labor Review*, June 2003, pp. 3–13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of *Employment and Earnings*, and “Recent changes in the State and Metropolitan Area CES survey,” *Monthly Labor Review*, June 2003, pp. 14–19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4- versus 5-week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12–17 in the *Review*). When all returns have been received, the estimates are revised and published as “final” (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Fourth-quarter data are pub-

lished as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on establishment survey data, contact the Division of Current Employment Statistics: (202) 691-6555.

Unemployment data by State

Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691-6392 (table 10) or (202) 691-6559 (table 11).

Quarterly Census of Employment and Wages

Description of the series

Employment, wage, and establishment data in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal agencies subject to the Unemployment Compensation for Federal Employees (UCFE) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Quarterly Census of Employment and Wages (QCEW) data, also referred as ES-202 data, are the most complete enumeration of employment and wage information by

industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor market trends and major industry developments.

Definitions

In general, the Quarterly Census of Employment and Wages monthly employment data represent the number of **covered workers** who worked during, or received pay for, the pay period that included the 12th day of the month. **Covered private industry employment** includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each ui-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (UCFE) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An **establishment** is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different NAICS industries.

Most employers have only one establishment; thus, the establishment is the

predominant reporting unit or statistical entity for reporting employment and wages data. Most employers, including State and local governments who operate more than one establishment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly ui report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the ui report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the **installation**: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers. Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into **size** categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level. It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total **wages** paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify

that wages be reported for, or based on the period during which services are performed rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as 401(k) plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wage per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual wage is affected by the ratio of full-time to part-time workers as well as the number of individuals in high-paying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of part-time workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

Notes on the data

Beginning with the release of data for 2007, publications presenting data from the Covered Employment and Wages program have

switched to the 2007 version of the North American Industry Classification System (NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Standard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past, the Covered Employment and Wage (CEW) program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England (and New Jersey).

The Office of Management and Budget (OMB) defines metropolitan areas for use in Federal statistical activities and updates these definitions as needed. Data in this table use metropolitan area criteria established by OMB in definitions issued June 30, 1999 (OMB Bulletin No. 99-04). These definitions reflect information obtained from the 1990 Decennial Census and the 1998 U.S. Census Bureau population estimate. A complete list of metropolitan area definitions is available from the National Technical Information Service (NTIS), Document Sales, 5205 Port Royal Road, Springfield, Va. 22161, telephone 1-800-553-6847.

OMB defines metropolitan areas in terms of entire counties, except in the six New England States where they are defined in terms of cities and towns. New England data in this table, however, are based on a county concept defined by OMB as New England County Metropolitan Areas (NECMA) because county-level data are the most detailed available from the Quarterly Census of Employment and Wages. The NECMA is a county-based alternative to the city- and town-based metropolitan areas in New England. The NECMA for a Metropolitan Statistical Area (MSA) include: (1) the county containing the first-named city in that MSA title (this county may include the first-named cities of other MSA, and (2) each additional county having at least half its population in the MSA in which first-named cities are in the county identified in step 1. The NECMA is officially defined areas that are meant to be used by statistical programs that cannot use the regular metropolitan area definitions in New England.

FOR ADDITIONAL INFORMATION on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691-6567.

Job Openings and Labor Turnover Survey

Description of the series

Data for the **Job Openings and Labor Turnover Survey** (JOLTS) are collected and compiled from a sample of 16,000 business establishments. Each month, data are collected for total employment, job openings, hires, quits, layoffs and discharges, and other separations. The JOLTS program covers all private nonfarm establishments such as factories, offices, and stores, as well as Federal, State, and local government entities in the 50 States and the District of Columbia. The JOLTS sample design is a random sample drawn from a universe of more than eight mil-

lion establishments compiled as part of the operations of the Quarterly Census of Employment and Wages, or QCEW, program. This program includes all employers subject to State unemployment insurance (UI) laws and Federal agencies subject to Unemployment Compensation for Federal Employees (UCFE).

The sampling frame is stratified by ownership, region, industry sector, and size class. Large firms fall into the sample with virtual certainty. JOLTS total employment estimates are controlled to the employment estimates of the Current Employment Statistics (CES) survey. A ratio of CES to JOLTS employment is used to adjust the levels for all other JOLTS data elements. Rates then are computed from the adjusted levels.

The monthly JOLTS data series begin with December 2000. Not seasonally adjusted data on job openings, hires, total separations, quits, layoffs and discharges, and other separations levels and rates are available for the total nonfarm sector, 16 private industry divisions and 2 government divisions based on the North American Industry Classification System (NAICS), and four geographic regions. Seasonally adjusted data on job openings, hires, total separations, and quits levels and rates are available for the total nonfarm sector, selected industry sectors, and four geographic regions.

Definitions

Establishments submit **job openings** information for the last business day of the reference month. A job opening requires that (1) a specific position exists and there is work available for that position; and (2) work could start within 30 days regardless of whether a suitable candidate is found; and (3) the employer is actively recruiting from outside the establishment to fill the position. Included are full-time, part-time, permanent, short-term, and seasonal openings. Active recruiting means that the establishment is taking steps to fill a position by advertising in newspapers or on the Internet, posting help-wanted signs, accepting applications, or using other similar methods.

Jobs to be filled only by internal transfers, promotions, demotions, or recall from layoffs are excluded. Also excluded are jobs with start dates more than 30 days in the future, jobs for which employees have been hired but have not yet reported for work, and jobs to be filled by employees of temporary help agencies, employee leasing companies, outside contractors, or consultants. The job openings rate is computed by dividing the number of job openings by the sum of employment and job openings, and multiplying that quotient

by 100.

Hires are the total number of additions to the payroll occurring at any time during the reference month, including both new and rehired employees and full-time and part-time, permanent, short-term and seasonal employees, employees recalled to the location after a layoff lasting more than 7 days, on-call or intermittent employees who returned to work after having been formally separated, and transfers from other locations. The hires count does not include transfers or promotions within the reporting site, employees returning from strike, employees of temporary help agencies or employee leasing companies, outside contractors, or consultants. The hires rate is computed by dividing the number of hires by employment, and multiplying that quotient by 100.

Separations are the total number of terminations of employment occurring at any time during the reference month, and are reported by type of separation—quits, layoffs and discharges, and other separations. Quits are voluntary separations by employees (except for retirements, which are reported as other separations). Layoffs and discharges are involuntary separations initiated by the employer and include layoffs with no intent to rehire, formal layoffs lasting or expected to last more than 7 days, discharges resulting from mergers, downsizing, or closings, firings or other discharges for cause, terminations of permanent or short-term employees, and terminations of seasonal employees. Other separations include retirements, transfers to other locations, deaths, and separations due to disability. Separations do not include transfers within the same location or employees on strike.

The separations rate is computed by dividing the number of separations by employment, and multiplying that quotient by 100. The quits, layoffs and discharges, and other separations rates are computed similarly, dividing the number by employment and multiplying by 100.

Notes on the data

The JOLTS data series on job openings, hires, and separations are relatively new. The full sample is divided into panels, with one panel enrolled each month. A full complement of panels for the original data series based on the 1987 Standard Industrial Classification (SIC) system was not completely enrolled in the survey until January 2002. The supplemental panels of establishments needed to create NAICS estimates were not completely enrolled until May 2003. The data collected up until those points are from less than a

full sample. Therefore, estimates from earlier months should be used with caution, as fewer sampled units were reporting data at that time.

In March 2002, BLS procedures for collecting hires and separations data were revised to address possible underreporting. As a result, JOLTS hires and separations estimates for months prior to March 2002 may not be comparable with estimates for March 2002 and later.

The Federal Government reorganization that involved transferring approximately 180,000 employees to the new Department of Homeland Security is not reflected in the JOLTS hires and separations estimates for the Federal Government. The Office of Personnel Management's record shows these transfers were completed in March 2003. The inclusion of transfers in the JOLTS definitions of hires and separations is intended to cover ongoing movements of workers between establishments. The Department of Homeland Security reorganization was a massive one-time event, and the inclusion of these intergovernmental transfers would distort the Federal Government time series.

Data users should note that seasonal adjustment of the JOLTS series is conducted with fewer data observations than is customary. The historical data, therefore, may be subject to larger than normal revisions. Because the seasonal patterns in economic data series typically emerge over time, the standard use of moving averages as seasonal filters to capture these effects requires longer series than are currently available. As a result, the stable seasonal filter option is used in the seasonal adjustment of the JOLTS data. When calculating seasonal factors, this filter takes an average for each calendar month after detrending the series. The stable seasonal filter assumes that the seasonal factors are fixed; a necessary assumption until sufficient data are available. When the stable seasonal filter is no longer needed, other program features also may be introduced, such as outlier adjustment and extended diagnostic testing. Additionally, it is expected that more series, such as layoffs and discharges and additional industries, may be seasonally adjusted when more data are available.

JOLTS hires and separations estimates cannot be used to exactly explain net changes in payroll employment. Some reasons why it is problematic to compare changes in payroll employment with JOLTS hires and separations, especially on a monthly basis, are: (1) the reference period for payroll employment is the pay period including the 12th of the month, while the reference period for hires and separations is the calendar month; and (2) payroll employment can vary from month

to month simply because part-time and on-call workers may not always work during the pay period that includes the 12th of the month. Additionally, research has found that some reporters systematically underreport separations relative to hires due to a number of factors, including the nature of their payroll systems and practices. The shortfall appears to be about 2 percent or less over a 12-month period.

FOR ADDITIONAL INFORMATION on the Job Openings and Labor Turnover Survey, contact the Division of Administrative Statistics and Labor Turnover at (202) 961-5870.

Compensation and Wage Data

(Tables 1–3; 30–37)

The National Compensation Survey (NCS) produces a variety of compensation data. These include: The Employment Cost Index (ECI) and NCS benefit measures of the incidence and provisions of selected employee benefit plans. Selected samples of these measures appear in the following tables. NCS also compiles data on occupational wages and the Employer Costs for Employee Compensation (ECEC).

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It is a Laspeyres Index that uses fixed employment weights to measure change in labor costs free from the influence of employment shifts among occupations and industries.

The ECI provides data for the civilian economy, which includes the total private nonfarm economy excluding private households, and the public sector excluding the Federal government. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Sample establishments are classified by industry categories based on the 2007 North American Classification System (NAICS). Within a sample establishment, specific job categories are selected and classified into about 800 occupations according to the 2000 Standard Occupational Classification (SOC) System. Individual occupations are combined to represent one of ten intermediate

aggregations, such as professional and related occupations, or one of five higher level aggregations, such as management, professional, and related occupations.

Fixed employment weights are used each quarter to calculate the most aggregate series—civilian, private, and State and local government. These fixed weights are also used to derive all of the industry and occupational series indexes. Beginning with the March 2006 estimates, 2002 fixed employment weights from the Bureau's Occupational Employment Statistics survey were introduced. From March 1995 to December 2005, 1990 employment counts were used. These fixed weights ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the series based on bargaining status, census region and division, and metropolitan area status, fixed employment data are not available. The employment weights are reallocated within these series each quarter based on the current ECI sample. The indexes for these series, consequently, are not strictly comparable with those for aggregate, occupational, and industry series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The ECI data in these tables reflect the conversion to the 2002 North American Industry Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. ECI series based on NAICS and SOC became the official BLS estimates starting in March 2006.

The ECI for changes in wages and salaries in the private nonfarm economy was pub-

lished beginning in 1975. Changes in total compensation cost—wages and salaries and benefits combined—were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (December 2005=100) are available on the Internet: www.bls.gov/ect/

ADDITIONAL INFORMATION on the Employment Cost Index is available at www.bls.gov/ncs/ect/home.htm or by telephone at (202) 691-6199.

National Compensation Survey Benefit Measures

Description of the series

NCS benefit measures of employee benefits are published in two separate reports. The annual summary provides data on the incidence of (access to and participation in) selected benefits and provisions of paid holidays and vacations, life insurance plans, and other selected benefit programs. Data on percentages of establishments offering major employee benefits, and on the employer and employee shares of contributions to medical care premiums also are presented. Selected benefit data appear in the following tables. A second publication, published later, contains more detailed information about health and retirement plans.

Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Employees are considered as having **access** to a benefit plan if it is available for their use. For example, if an employee is permitted to participate in a medical care plan offered by the employer, but the employee declines to do so, he or she is placed in the category with those having access to medical care.

Employees in contributory plans are considered as **participating** in an insurance or retirement plan if they have paid required contributions and fulfilled any applicable

service requirement. Employees in noncontributory plans are counted as participating regardless of whether they have fulfilled the service requirements.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

Notes on the data

ADDITIONAL INFORMATION ON THE NCS benefit measures is available at www.bls.gov/ncs/ebs/home.htm or by telephone at (202) 691-6199.

Work stoppages

Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 37.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved

in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

ADDITIONAL INFORMATION on work stoppages data is available at www.bls.gov/cba/home.htm or by telephone at (202) 691-6199.

Price Data

(Tables 2; 38–46)

Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period—December 2003 = 100 for many Producer Price Indexes (unless otherwise noted), 1982–84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 = 100 for International Price Indexes.

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993–95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 14 major urban centers are presented in table 39. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691-7000.

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in accordance with the North American Indus-

try Classification System and product codes developed by the U.S. Census Bureau.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691-7705.

International Price Indexes

Description of the series

The **International Price Program** produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during

the first week of the month. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard International Trade Classification (SITC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691-7155.

Productivity Data

(Tables 2; 47-50)

Business and major sectors

Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour,

output per unit of labor input, or output per unit of capital input, as well as measures of multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the quantity of goods and services produced per unit of capital services input. **Multifactor productivity** is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It

is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 47-50 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity; energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

Industry productivity measures

Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, **output** indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The **labor input** series is based on the hours of all workers or, in the case of some transportation industries, on the number of employees. For most industries, the series consists of the hours of all employees. For some trade and services industries, the series also includes the hours of partners, proprietors, and unpaid family workers.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. **Labor compensation** includes payroll as well as supplemental payments, including both legally required expenditures and payments for voluntary programs.

Multifactor productivity is derived by dividing an index of industry output by an index of combined inputs consumed in producing that output. **Combined inputs** include capital, labor, and intermediate purchases. The measure of **capital input** represents the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories. The measure of **intermediate purchases** is a combination of purchased materials, services,

fuels, and electricity.

Notes on the data

The industry measures are compiled from data produced by the Bureau of Labor Statistics and the Census Bureau, with additional data supplied by other government agencies, trade associations, and other sources.

International Comparisons

(Tables 51-53)

Labor force and unemployment

Description of the series

Tables 51 and 52 present comparative measures of the labor force, employment, and unemployment adjusted to U.S. concepts for the United States, Canada, Australia, Japan, and six European countries. The Bureau adjusts the figures for these selected countries, for all known major definitional differences, to the extent that data to prepare adjustments are available. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For further information on adjustments and comparability issues, see Constance Sorrentino, "International unemployment rates: how comparable are they?" *Monthly Labor Review*, June 2000, pp. 3-20, available on the Internet at www.bls.gov/opub/mlr/2000/06/art1full.pdf.

Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

Notes on the data

Foreign-country data are adjusted as closely as possible to the U.S. definitions. Primary areas of adjustment address conceptual differences in upper age limits and definitions of employment and unemployment, provided that reliable data are available to make these adjustments. Adjustments are made where applicable to include employed and unemployed persons above upper age limits and to exclude active duty military

from employment figures, although a small number of career military may be included in some European countries. Adjustments are made to exclude unpaid family workers who worked fewer than 15 hours per week from employment figures; U.S. concepts do not include them in employment, whereas most foreign countries include all unpaid family workers regardless of the number of hours worked. Adjustments are made to include full-time students seeking work and available for work as unemployed when they are classified as not in the labor force.

Where possible, lower age limits are based on the age at which compulsory schooling ends in each country, rather than based on the U.S. standard of 16. Lower age limits have ranged between 13 and 16 over the years covered; currently, the lower age limits are either 15 or 16 in all 10 countries.

Some adjustments for comparability are not made because data are unavailable for adjustment purposes. For example, no adjustments to unemployment are usually made for deviations from U.S. concepts in the treatment of persons waiting to start a new job or passive job seekers. These conceptual differences have little impact on the measures. Furthermore, BLS studies have concluded that no adjustments should be made for persons on layoff who are counted as employed in some countries because of their strong job attachment as evidenced by, for example, payment of salary or the existence of a recall date. In the United States, persons on layoff have weaker job attachment and are classified as unemployed.

The annual labor force measures are obtained from monthly, quarterly, or continuous household surveys and may be calculated as averages of monthly or quarterly data. Quarterly and monthly unemployment rates are based on household surveys. For some countries, they are calculated by applying annual adjustment factors to current published data and, therefore, are less precise indicators of unemployment under U.S. concepts than the annual figures.

The labor force measures may have breaks in series over time due to changes in surveys, sources, or estimation methods. Breaks are noted in data tables.

For up-to-date information on adjustments and breaks in series, see the Introduction and Appendix B. Country Notes in *International Comparisons of Annual Labor Force Statistics, Adjusted to U.S. Concepts, 10 Countries, 1997-2009*, on the Internet at www.bls.gov/ilc/flscomparelf.htm, and the Notes for Table 1 in the monthly report *International Unemployment Rates and Employment Indexes, Seasonally Adjusted, 2008-2010*,

on the Internet at www.bls.gov/ilc/intl_unemployment_rates_monthly.htm.

Manufacturing productivity and labor costs

Description of the series

Table 53 presents comparative indexes of manufacturing output per hour (labor productivity), output, total hours, compensation per hour, and unit labor costs for 19 countries. These measures are trend comparisons—that is, series that measure changes over time—rather than level comparisons. BLS does not recommend using these series for level comparisons because of technical problems.

BLS constructs the comparative indexes from three basic aggregate measures—output, total labor hours, and total compensation. The hours and compensation measures refer to employees (wage and salary earners) in Belgium and Taiwan. For all other economies, the measures refer to all employed persons, including employees, self-employed persons, and unpaid family workers.

The data for recent years are based on the United Nations System of National Accounts 1993 (SNA 93). Manufacturing is generally defined according to the International Standard Industrial Classification (ISIC). However, the measures for France include parts of mining as well. For the United States and Canada, manufacturing is defined according to the North American Industry Classification System (NAICS 97).

Definitions

Output. For most economies, the output measures are real value added in manufacturing from national accounts. However, output for Japan prior to 1970 and for the Netherlands prior to 1960 are indexes of industrial production. The manufacturing value added measures for the United Kingdom are essentially identical to their indexes of industrial production.

For the United States, the output measure is a chain-weighted index of real value added produced by the Bureau of Economic Analysis. BLS uses this series here to preserve international comparability. However, for its domestic industry measures, shown in tables 47–50 in this section, BLS uses a different output measures called “sectoral output,” which is gross output less intra-sector transactions.

Total hours refer to hours worked in all economies. The measures are developed from

statistics of manufacturing employment and average hours. For most other economies, recent years’ aggregate hours series are obtained from national statistical offices, usually from national accounts. However, for some economies and for earlier years, BLS calculates the aggregate hours series using employment figures published with the national accounts, or other comprehensive employment series, and data on average hours worked.

Hourly compensation is total compensation divided by total hours. Total compensation includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. For Australia, Canada, France, Singapore, and Sweden, compensation is increased to account for important taxes on payroll or employment. For the Czech Republic, Finland, and the United Kingdom, compensation is reduced in certain years to account for subsidies.

Labor productivity is defined as real output per hour worked. Although the labor productivity measure presented in this release relates output to the hours worked of persons employed in manufacturing, it does not measure the specific contributions of labor as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology, capital investment, capacity utilization, energy use, and managerial skills, as well as the skills and efforts of the workforce.

Unit labor costs are defined as the cost of labor input required to produce one unit of output. They are computed as compensation in nominal terms divided by real output.

Notes on the data

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available. For more in-depth information on sources and methods, see <http://www.bls.gov/news.release/prod4.toc.htm>.

Occupational Injury and Illness Data

(Tables 54–55)

Survey of Occupational Injuries and Illnesses

Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers’ job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both, because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

Notes on the data

The definitions of occupational injuries and illnesses are from *Recordkeeping Guidelines for Occupational Injuries and Illnesses* (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, *Occupational Injuries and*

Illnesses: Counts, Rates, and Characteristics.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691-6180, or access the Internet at: www.bls.gov/iif/.

Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety and Health Administration records, medical examiner and autopsy reports, media ac-

counts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses, which can be difficult to identify due to long latency periods.

Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 691-6175, or the Internet at: www.bls.gov/iif/

¹ The population figures are not seasonally adjusted.

² Civilian employment as a percent of the civilian noninstitutional population.

³ Beginning in 2003, persons who selected this race group only; persons who selected more than one race group are not included. Prior to 2003, persons who reported more than one race were included in the group they identified as the main race.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in January 2003, data reflect revised population controls used in the household survey.

¹ Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs.

² Includes data for Metropolitan Statistical Areas (MSA) as defined by OMB Bulletin No. 04-03 as of February 18, 2004.

³ Each year's total is based on the MSA definition for the specific year. Annual changes include differences resulting from changes in MSA definitions.

⁴ Totals do not include the six MSAs within Puerto Rico.

27. Annual data: Employment status of the population

¹ Cost (cents per hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

² Consists of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

³ Consists of legislative, judicial, administrative, and regulatory activities.

NOTE: The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

¹ Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:
M—Every month.

1—January, March, May, July, September, and November.

2—February, April, June, August, October, and December.

² Regions defined as the four Census regions.

³ Indexes on a December 1996 = 100 base.

⁴ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.

⁵ Indexes on a December 1986 = 100 base.

⁶ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the *CPI Detailed*

Report: Anchorage, AK; Cincinnati, OH—KY—IN; Kansas City, MO—KS; Milwaukee—Racine, WI; Minneapolis—St. Paul, MN—WI; Pittsburgh, PA; Portland—Salem, OR—WA; St. Louis, MO—IL; San Diego, CA; Tampa—St. Petersburg—Clearwater, FL.

⁷ Indexes on a November 1996 = 100 base.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date. Dash indicates data not available.

40. Annual data: Consumer Price Index, U.S. city average, all items and major groups

Dash indicates data are not available. Quarterly figures for Germany are calculated by applying an annual adjustment factor to current published data and therefore should be viewed as a less precise indicator of unemployment under U.S. concepts than the annual figures. For further qualifications and historical annual data, see the BLS report *International Comparisons of Annual Labor Force Statistics, Adjusted to U.S. Concepts, 10 Countries* (on the Internet at <http://www.bls.gov/lpc/ilscmparelf.htm>).

For monthly unemployment rates, as well as the quarterly and annual rates published in this table, see the BLS report *International Unemployment Rates and Employment Indexes, Seasonally Adjusted* (on the Internet at http://www.bls.gov/lpc/intl_unemployment_rates_monthly.htm). Unemployment rates may differ between the two reports mentioned, because the former is updated annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.

52. Annual data: employment status of the working-age population, adjusted to U.S. concepts, 10 countries

¹ Labor force as a percent of the working-age population.

² Employment as a percent of the working-age population.

³ Unemployment as a percent of the labor force.

NOTE: There are breaks in series for the United States (2003, 2004), Australia (2001), Germany (2005), the Netherlands (2003), and Sweden (2005). For further qualifications and historical annual data, see the BLS report *International*

Comparisons of Annual Labor Force Statistics, Adjusted to U.S. Concepts, 10 Countries (on the Internet at <http://www.bls.gov/ilc/flscompare.htm>). Unemployment rates may differ from those in the BLS report *International Unemployment Rates and Employment Indexes, Seasonally Adjusted* (on the Internet at http://www.bls.gov/ilc/intl_unemployment_rates_monthly.htm), because the former is updated annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.

¹ Data for 1989 and subsequent years are based on the *Standard Industrial Classification Manual*, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985–88, which were based on the *Standard Industrial Classification Manual*, 1972 Edition, 1977 Supplement.

² Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.

³ The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays;

EH = total hours worked by all employees during the calendar year; and

200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year).

⁴ Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.

⁵ Excludes farms with fewer than 11 employees since 1976.

NOTE: Dash indicates data not available.

55. Fatal occupational injuries by event or exposure, 1996-2005

Event or exposure ¹	1996-2000 (average)	2001-2005 (average) ²	2005 ³	
			Number	Percent

Fires and explosions	196	174	159	3
Fires--unintended or uncontrolled	103	95	93	2
Explosion	92	78	65	1

¹ Based on the 1992 BLS Occupational Injury and Illness Classification Manual.

² Excludes fatalities from the Sept. 11, 2001, terrorist attacks.

³ The BLS news release of August 10, 2006, reported a total of 5,702 fatal work injuries for calendar year 2005. Since then, an additional 32 job-related fatalities were identified, bringing the total job-related fatality count for 2005 to 5,734.

NOTE: Totals for all years are revised and final. Totals for major categories may include subcategories not shown separately. Dashes indicate no data reported or data that do not meet publication criteria. N.e.c. means "not elsewhere classified."
