The Evolving Structure of Female Work Activities: Evidence from the National Longitudinal Survey of Mature Women, 1967-1989

Donald O. Parsons
The Ohio State University

December 1994

Report: NLS 95-24

The National Longitudinal Surveys (NLS) program supports many studies designed to increase understanding of the labor market and methods of data collection. The Discussion Papers series incorporates some of the research coming out of the program. Many of the papers in this series have been delivered as final reports commissioned as part of an extramural grant program, under which grants are awarded through a competitive process. The series is intended to circulate the findings to interested readers within and outside the Bureau of Labor Statistics.

Persons interested in obtaining a copy of any Discussion Paper, other NLS reports, or general information about the NLS program and surveys should contact the Bureau of Labor Statistics, Office of Economic Research, Washington, DC 20212-0001, or call (202) 606-7405.

Material in this publication is in the public domain and, with appropriate credit, may be reproduced without pennission.

Opinions and conclusions expressed in this document are those of the author(s) and do not necessarily represent an official position of the Bureau of Labor Statistics or the U.S. Department of Labor.

# The Evolving Structure of Female Work Activities: <br> Evidence from the National Longitudinal Survey of Mature Women, 1967-1989 

Donald O. Parsons<br>The Ohio State University parsons.1@osu.edu

December 1994

This paper was funded by the U.S. Department of Labor, Bureau of Labor Statistics under small purchase order. The views expressed here are those of the authors and do not necessarily reflect the views of the U.S. Department of Labor.

The market work behavior of adult women in the United states has changed radically in the last several decades as a greater and greater share spend substantial time in the labor market. Despite this large time reallocation, comparatively little study has been devoted to the structure of the resulting work activities or to changes in that structure.... In this study, data from the Mature Women's Cohort of the National Longitudinal Survey is used to characterize the life cycle evolution of work structure from an annual perspective. Work is partitioned into four categories based on two work dichotomies: full- or part-time weeks and full- or part-time hours per week. Three "part-time" work possibilities exist in this framework: i) part-time weeks and full-time hours per week, ii) full-time weeks and part-time hours per week, and iii) part-time weeks and hours per week.

The analysis adopts a supply and demand framework. Employers have preferences for an employee's weeks per year and hours per week. Employer demands for weeks per year are likely to be influenced by seasonal and cyciical factors, while hours per week are likely to be affected by production and customer technologies. High training costs are likely to induce both greater weeks and greater hours per week. similarly the worker is likely to have preferences over the total time she supplies to the firm and how these are divided into weeks and hours per week. For women with small children, the structure of the school year and of the school day are both likely to be important.

The National Longitudinal Survey of Mature women provides a vaiuable data set for the investigation of recent trends in the structure of female work activity, including the growth of part-time work. It offers a quarter
of a century of detailed information on approximately 5000 female respondents 30 to 44 years of age in the first year (1967), and provides an important opportunity to explore the dynamics of work choices from midife to the eve of retirement for the entire sample and into the retirement period for a substantial subset of the sample during the time of this great transition. The study focuses on the 1967-1989 period at the end of which time the respondents were 52 to 66 years of age.

Major findings of the analysis include:

1) The most obvious trend in work-time structure over the 1967-1989 pexiod for the Mature Women's cohort is the life cycle shift from no work to full-time (full-time weeks and full-time hours per week) and then back again. The percent of all respondents who work full-weeks and hours rises from 27 percent in 1967 to 40 percent in 1977 before falling to 28 percent in 1989. Conversely the percent not working at all falls from 48 percent in 1967 to 39 percent in 1982 before rising again to 49 percent in 1989. There is also a major shift out of part-year/fullweek work and into full-year/part-week work between 1967 and 1972 that persists persists throughout the sample period.
2) Among employed women, the most obvious phenomena in this data are i) the life cycle sensitivity of part-year work (the midlife shift from part-year to full-year work and return) ; and ii) the secular increase in full-year/part-week status, which doubles between 1967 and 1977 (to 19 percent of all employed respondents).
3) Large and sustained differences in work-time structure exist across industries-istrong evidence that the employer's preferences are important. Manufacturing, for example, offers few part-time hours jobs. Ninety-three percent of all employees in that sector work full-time hours, though a significant share, 28 percent work less than forty weeks a year. This pattern is consistent with a great deal of specialized training and a relatively institutional work structure that admits iittle diversity. Conversely in the wholesale añd retail sector, 35 percent of all employees work less than 35 hours a week; in the professional sector 26 percent; and in personal services 47 percent.
4) Part-year work appears to be driven by seasonal and cyclical factors. Industries such as agriculture and manufacturing have large numbers of employed female workers who usually worked fuil hours but for less than forty weeks in the year. Agriculture, wholesale and retail, personal services, and the entertainment industries have the greatest number of "casual" jobs, those with part-year and part-week employment. This no doubt reflects strong seasonal factors. Among the larger employment
sectors, personal services and to a lesser extent wholesale and retail stand out as especially likely to offer part-time hours but full weeks.
5) At the individual level, the polar states-no work and full-time work-are quite stable over five year periods. Eighty percent of the nonworkers and two-thirds of the full-time workers were in the same state five years later. Among the various combinations of part-time states, part-year or part-week, only the full-year/part-week state was stable, with 40 percent of these found in the same state five years later. The other categories, especially casual work (part-year AND part-week), are transitory states, at least from a five year perspective. Only ten percent of the casual workers in the first period were casual workers five years later.
6) Casual work (part-time weeks and hours) would appear to be a stepping stone to more stable work commitments. Among casual workers in 1967, fifty percent were split more or less equally between full-year/partweek work and full-Year/full-week work in 1972. About one-third were not working. Conversely two-thirds of the respondents who were in casual jobs in 1972 were out of the labor force five years earlier. Few full-year workers return to casual, part-year and part-week, work.
7) Marital disruption increases labor market activity. It is natural to imagine that the withdrawal of the husband from the labor force would have the same labor market effect on the spouse as a marital disruption since the family income effect is the same in both cases-loss of husband's earnings. Such is not the case. Not only is the rate of entry into full-time work not increased with the departure of the husband from the work force, it shrinks. The likelihood that a respondent who is married with spouse present will be working full-time in 1989 is cut in half if the husband is not in the labor force. The_evidence is consistent with the hypothesis that this is due to greater home nursing demands on the woman.
8) Less work intensity in the pre-retirement years increases the early retirement rate. The average work withdrawal rate of the various parttime categories is twice that of full-time workers in the eariy retirement period. This is despite the limited pension coverage among part-time workers. Although there are significant year-to-year fluctuations in pension coverage, especially in the smaller work status categories, the general pattern is one in which the most casual employees (PYR/PWK) have only one fourth the coverage of the full-time workers (FYR/FWK). More interesting, perhaps, the FYR/FWK workers have coverage only modestly higher than the PYR/PWK workers, 28 percent versus 22 percent. In contrast, the PYR/FWK workers have coverage rates that, while less than full-time workers, are double those of the other PYR categories. Apparently a full work week is the crucial pension eligibility factor.
I. Introduction

The market work behavior of adult women in the united states has changed radically in the last several decades as a greater and greater share spend some time in the labor market. Despite this large time reallocation, comparatively little study has been devoted to the structure of the resuiting work activities or in changes in that structure. Important exceptions include the work of Hanoch (1980a, 1980b) and Blank (1988, 1989, 1990) on part-time work. In most studies part-time work is defined as a work week that is less than 35 hours. ${ }^{1}$ The rationale for characterizing the work environment with this measure is rarely specified. Certainly ie does not correspond to. the typical respondent's planning horizon. Viewed from a jonger time perspective, perhaps a year, "part-time work" could just as easily involve full time hours for a. Iimited number of weeks, Mellor and Parks (1988). In this paper I use both the hours and weeks dimensions of labor force activity to characterize the work activity of mature women, focusing on the long term dynamics of these activities. ${ }^{2}$

The National Longǐtudinal Survey of Mature Women provides a rich data set for the investigation of recent trends in the structure of female work activity, including the growth of part-time work. It offers a quarter of a century of detailed information on approximately 5000 female respondents 30 to. 44 years of age in the first year (1967), and provides an important opportunity to explore the dynamics of work choices from midifife to the eve of retirement for the entire sample and into the retirement period for a substantial subset of the sample during the time of this great transition. The
study focuses on the 1967-1989 period at the end of which time the respondents were 52 to 66 years of age.

The analysis first describes the hours/weeks experiences of the NLS Mature Women's Cohort from a demand and supply perspective. The panel aspect of the data is then exploited to describe the dynamics of the hours/weeks work structure. How stable is the hours/weeks work structure over long intervals of time? ${ }^{3}$ How does the composition of work activities change with changes in family circumstances, e.g. the maturing of her family, marital disruption, or the change in the labor foree status of her husband? What insights into the crucial market reentry process can be found in the patterns of job transitions? ${ }^{4}$

The paper proceeds in the following way. In section I' $\mathbf{I}$ present a brief outline of the economic forces that mold the hours/weeks work decision. I also provide descriptive statistics on observed work hours and weeks worked per year among the NLS respondents. These data provide the framework for the consideration of the structural (joint hours/weeks) analysis that begins in section III. After characterizing various static aspects of the evolution of work structure, I turn in Section IV to consideration of demand aspects of this structure, including industrial differences in work status. In section $V$ I develop the dynamics of hours/weeks work activity, including an assessment of major family changes on transition probabilities, concluding in section VI with some observations on the change in work dynamics during the early retirement period and the implications of earlier work structure decisions on the availability of retirement income.
II. Work Hours, Work Weeks, and The Labor Market

## A. A. Brief Theoretical Overview

Demand and supply forces tend to be channeled through the labor market in a very special way. Jobs with specific attributes are set by the firm and workers choose the job with the attributes that they most value among the jobs available to them. The job attributes offered by the firm may be more or less rigidly set, depending on the advantages the firm can extract from the attribute. If the technology is flexible along dimensions important to the worker, the firm will tend to adjust its job demands in ways the worker finds attractive. If the technology is not flexible, it will be forced to pay higher wages to compensate the worker for unattractive job characteristics, Altonji and Paxson (1989).

The firm's demand for job characteristics such as part-time/full-time, defined either in hours per week or weeks per year, are set by the firm and its technological and product market circumstances. The need for specialized training will be a factor in both the hours and weeks decision, with the firm trying to limit hiring and training costs by having the worker put in more time with the firm. Hours per week will be affected by the nature of daily production in a goods producing firm and by access to customers in service producing firms. ${ }^{5}$ part-time hours may even be valued by the firm in the second case despite the additional fixed costs of training, payroll book-keeping, etc. The firm's demand for weeks per year may be determined by some of the same forces-ceteris paribus, high training jobs will tend to be full-year jobs-but is also likely to be strongiy affected by seasonal and cyclical variations in product demand and in cooperating factors.

The worker is likely to have preferences over the hours per week and the.weeks per year that characterize a "job". Ceteris paribus, she will accept a lower-wage for jobs that mesh well with child care demands in the household. In a daily framework that means she will prefer jobs that offer hours during the school day. In a weekly frame, she will prefer jobs that demand her time only during the school year. Child care demands introduce an important life cycle aspect into the woman's hours and weeks choices. As the woman ages, child care demands fall, which should induce not only more work but a greater demand for full-time jobs. Negative economic events in the household, most prominently marital disruption and husband's disability also may alter the type of job the respondents demand.
B. Work Hours per Week and Work Weeks Per Vear: Recent Trends

The calendar year is a natural planning horizon, even in the inaustrial world, and it is natural to imagine that the househoid might determine annual hours, not simply weeks per year or hours per week. ${ }^{6}$ Indeed hours and weeks become two parts of a planning vector in the annual framework adopted here. Nonetheless it will be useful to look at important aspects of these two dimensions of work activity separately. Before doing so however, a description of the data, the NLS Mature Women's Cohort is in order. The Data. As noted above, the NLS Mature Women's cohort is a panel survey that began with approximately 5,000 women between the ages of 30 and 44 at the time of the first interview in 1967 . These women have been reinterviewed every year or two through 1992, although data was available only through the 1989 survey at the time the bulk of the empirical work was undertaken for this study. In order to highlight long term processes, the analysis focuses on five year transitions over the twenty-two year period

1967-1989, neglecting shorter term fluctuations in employment status. In particular the study estimates work status transitions over the years 1967-1972-1977-1982-1987-1989. Extended face-to-face inteviews were conducted with respondents in each of these years.

Ali statistics in this paper are weighted by NLS population weights to correct for the initial sampling design, including an oversampling of blacks, and for differential attrition (comparable unweighted statistics can be found in the relevant statistical summaries that accompany this report). The frequencies reported in the various tables are normalized to the original population frequencies to give some idea of the number of observations underpinning the table data. Because of rounding error in the computations, the frequencies within a table will not necessarily sum to the total, although they should be close. The addition of entries across tables will not sum to the total and need not even be close. For example in the weighted transition matrices, the sum of the reported number of blacks and whites who exit a work state is not the total number exiting that state, even after adjusting for the small number of other races in the survey, because the weighted frequencies in the black and white tables are normalized by the raw numbers of blacks and whites in the survey, not the weighted numbers. The statistics by race add to the total. frequencies after the raw numbers of blacks and whites are appropriately weighted.

Work Hours per Week. In Table I I report the distribution of work hours per week for respondents at five year invervals for 1967 to 1987 arid in 1989. The hours pattern in 1967 is similar to those in later years. In 1967 relatively few respondents work less than a twenty hour week--10 percent in 1967--perhaps because of the fixed costs of work activities. Somewhat more, 15 percent, worked $\overline{2} \overline{0}$ to $\overline{3} 4$ hours, with three quarters working $\overline{3} \overline{5}$ hours or
more. The work hours distribution changed little over the 22 years of the sample. Between 1972 and 1987 , the fraction working full-time varied between 72 to 73 percent. Only in 1989 , as the oldest respondents reached traditional retirement ages, does the fraction working full-time fall to 68 percent.

The distribution of hours for employed respondents were remarkably similar for whites and blacks. In 1967 75 percent of employed white respondents worked 35 or more hours per week, 15 percent worked 20 to 34 hours per week, and 10 percent worked less than 20 hours. For black women the percentages are 72 percent, 16 percent, and 12 percent.-. By the end of the period (1989) the corresponding statistics for whites were 73 percent, I9 percent, and 8 percent; for blacks 74 percent, 17 percent, and 10 percent. In many ways the most remarkable feature of these statistics is the similarity in work hours, given the large differences in family structure and total family income between the two groups.

Blank has reported that work hours activities are quite stable over short periods, Blank (1989). The NLS data indicates that is the case over long periods as well. In Table 2, I report the work hours transition matrices for the five year interval 1967-1972 in total and by age groupings and race. Matrices for other periods are similar. Important definitions include:

| Age $=1$ |  | Cohort members who were $30-34$ in 1967 |
| :--- | :--- | :--- |
| Age $=2$ |  | Cohort members who were $35-39$ in 1967 |
| Age $=3$ |  |  |
| Race $=1$ |  |  |
| Race $=2$ |  | Race white |
| Race $=3$ |  | Race black |
| Other races |  |  |

The transition matrix for the full sample reveals that 88 percent of fulltime employed workers (working 35 or more hours a week) in 1967 who were employed in 1972 were working full-time then as well. Among those working 20 to 34 hours per week in the first year; almost 60 percent were working full-time five years later, but 32 percent continued to work 20-34 hours per week. Among those on especially short hours (1-19), 33 percent continued to work 1-19 hours, 25 percent were working $20-34$ hours, and 42 percent were working full-time. Clearly there is a great deal of hours persistence even over a period as long as five years.

Weeks Worked. The second dimension of work activity examined here is the number of weeks worked in a year or more generally the percent of weeks worked in the interview frame. The first NLS survey collected weeks worked in the year prior to the interview and so has a standard 52 week framework for each individual. Subsequent surveys collected data on the weeks worked since the last survey and weeks since the last survey, which varies across the surveys on average, because some surveys were one year apart, others Ionger, and by individual, depending on when they were interviewed in each round. To provide a standard format For each year, the percent of weeks worked was computed as the number of weeks worked divided by the number of weeks in the survey time frame.

The distribution of weeks worked for the survey years 1967, 1972, 1977, 1982, 1987, and 1989 are reported in Table 3. The well-known bi-polarity of weeks worked is evident in all years-more than 80 percent of all respondents either did not work at all or worked more than three quarter of all weeks. The remaining 15 to 20 percent of the sample is almost uniformiy spread over the three intermediate categories-1-1-25\%, 26-50\%, and 51-75\%. There is also the expected life cycle pattern of increasing full-time work
and decreasing part-time work in the earlier years (through 1982) as the women return to the labor force as their children matire and require less child care and then withdraw again as they pproach or reach traditional retirement ages. Working some but less than 76 percent of all weeks appears to shrink over most of the sample period, although more strongly in the first time intervals. This observation is consistent with the argument that part-time weeks are a response to child rearing responsibilities.

There is a remarkable convergence of weeks worked between white and black females in the sample, Table 4 . In 1967 black women were working substantially more than their white counterparts. Forty-nine percent of black women, but only 35 percent of white women worked more than three-quarters of the weeks available. By 1989, the percentages were 40 percent and 41 percent for blacks and white respectively. In 196746 percent of whites but oniy 27 percent of blacks did not work at all. By 1989 the percentages were 44 percent for white and 47 percent for blacks. This convergence of work activity has occurred despite the persistence of large differences in education levels and average family income of the two groups.

There appears to be a great deal of change in work week intensity over long periods of time. The distribution of cumulative weeks worked over the period 1967-1989 is much less bipolar than are the individual year distributions, Table 5. The cumulative weeks worked measure is derived from the total weeks worked and the total weeks in the sample frame for the six surveys 1967, 1972, 1977, 1982, 1987, and 1989. Only 14 percent of the sample reported no weeks worked over this period; only 27 percent worked more than eighty percent of available weeks. The remaining sample members are more or less equally distributed over the intervening categories.

Work week mobility can be measured more directly using five-vear transition matrices. Focusing again on the 1967-1972 transitions, the fraction of weeks worked in 1972 is strongly, but imperfectly correlated with 1967 work rates, Table 6. The percentage not working in 1972 fell from 63.3 percent of those not working in 1967 to 29.9 percent among those who worked less than 25 percent of all weeks, and to 27.7 percent, 19.6 percent, and 10.9 percent as the 1967 work week commitment increases. Conversely. the percent working full-time in 1972 rises from 22 percent to 77 percent over the same range of 1967 categories. The transition matrices for blacks and whites are also quite similar. Again see Table 6.
III. The Evolving Structure of Female Work Time

Annual hours have both a week and an hours per week component and the brief analyses of the preceding section make it clear that the two need not proceed in lock step. ${ }^{7}$ Much useful structural information would be lost if we simply adopted an annual hours measure of work activity. We consider instead a four-way classification of jobs:

> PYR/PWK $=$ part-year and part-week work;
> PYR/FWK $=$ part-year and full-week;
> FYR/PWK $=$ full-year and part-week; and
> FYR/FWK $=$ full-year and full-week;
where:

$$
\begin{aligned}
\text { part-week }= & \text { work week of less than } 35 \text { hours; and } \\
\text { part-year }= & \text { weeks worked since last survey that is less than } \\
& 76.9 \text { percent }(40 / 52) \text { of all weeks available. }
\end{aligned}
$$

The decision to treat full year work as forty or more weeks per year is somewhat arbitrary but is designed..to include as full-time workers those who may have unpaid summer vacations, e.g. teachers.

Before turning to the analysis of the NLS Mature Women Panel, it will be useful to review population trends in work structure in this period. Mellor and Park (1988) compile such information over the 1966-1986 period using March CPS annual work experience data. They use as their definition of "part-year" work a work week of less than 50 weeks, so the magnitudes of the work structure measures are not strictly comparable to those reported here for the NLS panel, but the trends should be comparable.

WORK STATUS OF EMPLOYED WORKERS, WOMEN
PYR/PWK PYR/FWK FYR/PWK FYR/FWK

| 1967 | $19.5 \%$ | $28.4 \%$ | $9.9 \%$ | $42.1 \%$ | $100.0 \%$ |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1972 | 20.5 | 26.6 | 10.3 | 42.5 | $100.0 \%$ |  |
| 1977 | - | 21.8 | 25.0 | 11.1 | $42.1 \ldots$ | $100.0 \%$ |
| 1982 | 20.3 | 20.8 | 12.9 | $45.9 \%$ | $100.0 \%$ |  |
| 1986 | 19.0 | 18.8 | 12.7 | 49.5 | 100.1 |  |

Source: Mellor and Parks (1988, Table 1)
Summarizing these results, there has been a trend toward full-year, fullweek jobs, especially since 1982; there has been a large decline in partYear, full-week jobs; there has been a modest upward drift in full-year, part-week jobs; and no trend of note in the prevalence of part-year, partweek jobs. To the extent the NLS panel trends differ from these in a substantial way, the disparity is most probably due to iffe cycle effects.

The structure of female work-time, including nonworkers, is reported at each of the five year interval survey dates in Table $\overline{7}$. The most obvious trend in work-time structure over the 1967-1989 period for the Mature Women's cohort is the shift from no work to full-time work and then back again. The percent of all respondents who work full-time rises from 27 percent in 1967 to 40 percent in 1977 before falling to 28 percent in 2989. Conversely the percent not working at all falls from 48 percent in 1967 to 39 percent in 1982 before rising again to 49 percent in 1989. Clearly there are strong iffe cycie effects here. There is also a major shift out of part-year/full-week work and into full-year/part-week work between 1967 and 1972. This shift toward full-year/part-week work persists throughout the sampie period.

Table 7 reveals the high correlation of part-year and part-week work. Of those who work part-year in 1967, 36 percent (6.9\%/19.2\%) also work part-week. Of respondents who worked fuli-year in 1967, only 17 percent worked part-week. In 1972 the likelihood of part-week work was inigher for both year categories, but was again approximately twice as great for the part-year workers--46 percent versus 24 percent.

The data from Table 7 can be recomputed to provide estimates of the structure of work activity for working respondents, permitting a comparison with Melior and Parks' population figures:

All statistics are weighted.
Source: Table 7

Among the most obvious phenomena in this data are i) the life cycle sensitivity of part-year work (the midlife shift from part-year to full-year work and return) ; and ii) the increase in full-year/part-week status, which doubles between 1967 and 1977. (to 19 percent of all employed respondents). This cohort of employed female respondents were much more likely to hold jobs that offer regular employment at part-time hours in the later years of the survey.
IV. The Industrial Determinants of the Time Structure of Jobs

In this section I examine the demand side of the market, looking at the industrial correlates of the work-time structure of jobs. As discussed in Section II, employers are not necessarily indifferent to the work time of their workers. Both the weeks worked in the year and the hours worked in the week are jointly determined by the employer's and worker's preferences. To the extent the employer has rigid work time requirements that deviate
from the workēr's preferences, perhaps because of large hiring and training costs or of special attributes of the production process or customer base, she presumably compensates the worker. The work time structure will refiect the employer's preferences in this case. In situations in which the employer can cheapiy accommodate the worker's preferences, work time will instead reflect those preferences.

Large differences in work-time structure across industries is strong evidence that the employer's preferences are important, aithough industrial patterns couid emerge as the aggregation of different skill land labor supply) mixes. In Tables 8 through 10, I report the structure of work across one-digit industries for 1967, 1977, and 1989. Clearly there are major differences in work-time structure across industries. Manufacturing, for exampie, offers few part-week jobs. Ninety-three percent of all employees in that sector work full-time hours, though a significant share, 28 percent work less than forty weeks a year. Still sixty-six percent work full-hours and full weeks. This pattern is consistent with a great deal of speciaiized training and a relatively institutional work structure that admits littile diversity. Conversely in the wholesale and retail sector, 35 percent of all employees work less than 35 hours a week; in the professional sector 26 percent; and in personal services 47 percent.

Part-year work appears to be driven by seasonal and cyclical factors. Industries such as agriculture and manufacturing have large numbers of employed female workers who usually worked full hours but for less than forty weeks in the year. Agriculture, wholesale and retail, personal services, and the entertainment industries have the greatest number of "casual" jobs, those with part-year and part-week employment. This no doubt reflects strong seasonal factors. Among the larger employment sectors, personal
services and to a lesser extent wholesale and retail stand out as especially likely to offer part-time hours but full weeks.

Below I sumamize some key statistics in three industries that employ large numbers of mature women, namely manufacturing, wholesale and retail, and professional services.

WORK STATUS

$$
\text { PYR/PWK } \quad \mathrm{PYR} / F W K \quad F Y R / P W K \quad F Y R / F W K

| 1989 | 10.4 | $\ldots$ | 15.9 | 19.8 | 55.9 |

All statistics are weighted.
Over the 1967-1989 period the relative employment share of manufacturing has fallen, while those of wholesale and retail and professional services, especially professional services, have increased sharply. Reviewing these statistics, one is struck by the life cycle volatility of part-year work: the shift out of part-time work in midiffe is quite large. The aggregate shift into full-year/part-week work (FYR/PWK) noted earlier is not evident
in all industries. Indeed in manufacturing, the work-time distribution changed very little between 1967 and 1989. In both the wholesale anc retail sector and the professional sector, however, there were large shifts from PYR/FWK to FYR/PWK. Indeed much of the overall shift toward full-year/partweek work status comes from these two sectors.
V. Individual Dynamics

The fact that there are pronounced differences in industrial work hours does not mean that the NLS respondents could not change their work commitments, but rather that they probably had to change jobs, if not empioyers, to do so. How stable are the work-time choices of these mature women? Perhaps even more important from a policy perspective is the behavior of new entrants to the job market. Must new entrants enter the market through part-time work, gradually working their way into full-time positions, or do they move directly into full-years and weeks jobs? Of special interest here is the importance of the hours/weeks distinction in job evolution. Seniority ruies almost insure that new entrants will work less weeks in a Year; even if they wanted to work full-time, they often can not. Hours are a quite different matter. Blank (1989) presents evidence that suggests workers do not use part-week work as a stepping stone to full time hours. We will take up the two issues in turn.

Five year work status transition matrices are reported in Tables II-I4 for 1967-1972, 1972-1977, 1977-1982, and 1982-1989 respectively. The work status transition tables are reported in total, by age and race. Recall again that i) Age=1,2,3 denotes women 30-34, 35-39, and 40-44 in 1967
respectively and ii) Race=1 denotes whites, Race $=2$ blacks. The Iarge number of parameters in these tables appears somewhat daunting at first, so it might be useful to focus on some key ones. For example the retention rates within each job status category, essentially the diagonal of the transition matrix, provide a measure of the stability of each work status category. These are:

Five Year Work Status Retention Rates 1967-72. 1972-77 1977-82 1982-87 AVE

Work Status:

| NONE TO NONE | $68.8 \%$ | $77.2 \%$ | $80.5 \%$ | $89.6 \%$ | $79.0 \%$ |

| All statistics are weighted. |  |  |  | 74.1 |  |

Work Status stability. Clearly the polar states, no work and full-time work, are quite stable over five year periods. Eighty percent of the nonworkers and two-thirds of the full-time workers were in the same state five years later. Among the various combinations of part-time states, part-year or part-week, only the full-year/part-week state was stable, with 40 percent of these to be found in the same state five years later. The other categories, especially casual work (part-year AND part-week), are transitory states, at least from a five year perspective. Only ten percent of the casual workers in the first period were casual workers five years later.

Where did the part-time workers go? The transition parameters are relatively stable across years and it may be safe to focus on one of them,
say 1967-1972, Table 11. Among casual workers in 1967, about one-third were out of the labor force. Another fifty percent were split more or less equally between full-year/part-week work and full-year/full-week work. In that sense casual work would appear to be a stepping stone to more stable work commitments. Certannly few of the full-year workers "return" to casual labor, defined as part-year and part-week work. Two-thirds of the respondents who were in casual jobs in 1972 were out of the labor force five years earlier (101/I68).

Job Entry. Given the importance of the entry process, it will be useful to consider the mechanism more carefully. How do those out of the market return? Is it directly into full-time employment or are they likely to secure part-year or part-weeks work first? One way to isolate the entry efEect is to compare the work-time structure of new entrants with the worktime structure of all employed workers. The work-time distribution for all employed respondents can be calculated by dropping the no work category in Table 7 and renorming the remaining entries. These are reported above but reported for convenience of comparison in Table 15, Panel A. Similar work status breakdowns for new entrants, those who were not employed five years before, can be constructed from the appropriate entries in Table 11-14. These are reported in Table 15 , Panel $B$. The distributions are quite different. Of those with a job in 1967 , almost two-thirds were employed in full-time (weeks and hours) work, while only 40 percent of new entrants were in such jobs. About one-third of all new entrants end up in full-year/partweek jobs, with the remainder to be found primarily in casual jobs. clearly entrants do not take a random draw of jobs, but enter disproportionately through part-time work, especially full year/part week jobs.

What can be presumed to be aging effects are also evident in the new entrant table. New entrants have a declining likelihood of full-time work as they age, with the percent entering full-time work steadily declining from 40 percent to 30 percent. This could be because the respondents want less intense work as they age or because they have trouble securing intense ones.

Although I have to this point stressed the stability of work-time status--for full-time work and no work and to a lesser extent full-year/part-week work--that should not disguise the substantial turnover that does occur between work-time categories. Between 1967 and 1972 , for example, more than 30 percent of the respondents who were out of the labor force in 1967 were working in some type of job in 1972 , about 12 percent in fuli-time jobs, Table ll. Of those in full-time work in 1967, almost one quarter were either in jobs limited in weeks or hours or not employed at all in 1972.

In the remainder of this section, I will consider several factors that may induce change in work status. Plausible hypotheses are easy to enumerate. Some are related to predictable Iife cycle phenomenon, e.g. the maturation of the children, freeing family time that would otherwise be absorbed in child care, and the withdrawal from the labor force at traditional retirement ages. Others-most obviousiy marital disruption or the onset of a disability that limits the husband's work opportunities-are random events, against which the respondent is often underinsured. All may alter the respondents' work-time patterns. I consider three of these in this section and the fourth, the retirement process, in the next.

Maturing Children. For most of the respondents, who were age 30 to 44 in 1967, child care responsibilities decline consistentiy and predictably
throughout the iife of the panel and it is reasonabie to conjecture that these women on average return to the labor force as the demands on their time at home shrink. The data on work-time structure by age of youngest child in 1967, Table 16, strongly confirms this conjecture. For respondents with children under two years of age, 72 percent were out of che labor force. Of the remainder, seventy percent were involved in part-time work of some type, with PYR/FWK the most popular option. Only 9 percent were in full-time (weeks and hours) work. By way of contrast, only 27 percent of respondents with no children were out of the labor force and more than half were working full-time. Full-time work systematically increases as age of youngest child increases. Almost 30 percent of the respondents with children 6 to 18 years of age were working full-time, a three-fold increase over respondents with the youngest child less than 2.

Marital Disruption. Marital disruptions often impose major finānćalal losses on respondents, which in turn are likely to stimulate greater labor force activity. The impact of marital disruption on changes in work activity between 1967 and 1.989 are reported in Table 17 . In this table, marital state is described by a zero-one dichotomous variable MSP equal to one if the respondent reports being married with spouse present, zero otherwise. In panel A of this table, the 1967-1989 work status transition matrix is computed in total and for the four possible marital transitions-married in 1967 and 1989 (MSP67/MSP89); married in 1967 but not in 1989 (MSP67/NMSP89); not married in 1967 and married in 1989 (NMSP67/MSP89); and unmarried in both years (NMSP67/NMSP89).

There is strong evidence that marital disruption does increase labor market entry. In 1989, 23 percent of those whose marriages were intact were in full-time work; of those with disrupted marriages 37 percent were in

```
full-time work. This pattern is evident for the entry rates into full-time
employment independent of initial work state forstable and disrupted mar-
riages:

SOURCE: Table 17
Not oniy are respondents who were not working in 1967 more likely to be full-time workers in 1989, those who were already working full-time were ten percentage points more likely to stay employed full-time (4i percent versus 29. percent). The reverse holds for exit from the labor force. Respondents in stable marriages were slightly more likely to be engaged in part-time work of one type or another than were those in disrupted marriages.

#### Abstract

Labor Force Withdrawal of the Husband. It is natural to imagine that the withdrawal of the husband from the labor force would have the same Iabor market effect on the spouse as a marital disruption since the major economic effect is the same in both cases-loss of husband's earnings. Such is not the case, however, Table 17 . The behavioral difference between disrupted

marriages and stable ones with a nonworking husband becomes quite clear if we construct data comparable to that immediately above, describing the rate of entry into full-time work by work status:

SOURCE: Table 17
Not oniy is the rate of entry into full-time work not increased, it shrinks. The likelihood that a respondent will be working full-time in 1989 is cut in half if she is married but the husband is not in the labor force.

This may partly resuit from complementarities in leisure between wives and husbands. If the husband withdraws voluntarily (retires), the wife may retire as well. A large number of labor force withdrawals at this age are not voluntary, however, but are due to the onset of a disability. What this suggests is the importance of wife nursing activities. When the husband is forced to withdraw from the labor force for reasons of poor health, the wife may find that the demands on her home time increase more dramatically than do the demands for her work time, Parsons (1977). The work differentials between married respondents whose husbands are in the labor force and those
who are not differ by age in a way that is at least consistent with the nursing hypothesis. At the younger ages, when the husband's withdrawal is most likely to be health related, the differentials are greatest. Among those 30 to 34 years of age in 1967 (52-56 in 1989), for example, the Iikelinood of a married woman being in full-time work is 39 percent among respondents whose husbands were in the labor force in both 1967 and 1989; among those whose husbands dropped out of the labor force between 1967 and 1989, only 30 percent were in full-time work in 1989. For chose 35-39 in 1967 (57-61 in 1989), the comparable statistics are 27 percent and 17 percent, but for those $40-44(62-66$ in 1989$)$ 12 percent and 8 percent respectively, for a differential of only 4 percent.
VII. Work Structure and the Retirement Mechanism

#### Abstract

Retirement Behavior. It is not clear a priori how work structure influences retirement rates. On the one hand, one could conjecture that part-time workers are less committed to the labor force and therefore are more likely to withdraw as they reach traditional retirement ages. On the other hand, one could imagine that part-time workers might find it easier to continue working into the retirement years. The five-year transition matrices for the 1982 to 1987 interval provide evidence on this question. The full tables are reported above in Table 14. Below I summarize the probability that the respondent will not be working in 1987 as a function of work status in 1982, in total and by the three age brackets, 50-54, 55-59, and 60-64 in 1987:

> Percent of Respondents Not Working in 1987 By Prior Work Status (1982) and Age in 1987

Age 87: : 50-54 55-59 60-64 TOTAL
Woris Status 82

| NONE | $85.1 \%$ | $84.4 \%$ | $96.2 \%$ | $89.6 \%$ |
| :--- | :---: | :---: | :---: | :---: |
| PYR/PWK | $31.1 \%$ | $59.8 \%$ | 51.4 | 46.9 |
| PYR/FWK | 20.1 | -- | 24.4 | 67.1 |
| FYR/PWK | 14.6 | 19.9 | 34.3 | 38.5 |
| FYR/FWK | 7.7 | 17.1 | 30.4 .6 | 17.9 |
| AII | 33.8 | 46.1 | 64.3 | 48.8 |

All statistics are weighted.

The evidence supports the conjecture that less work intensity in the preretirement years increases the early retirement rate. The average work withdrawal rate of the various part-time categories is twice that of the full-time workers. Although the levels of not working are higher in each category than earlier transitions-by the age of 60 almost no female respondents were working who were not working five year previously--the basic structure of nonwork rates across work status categories is not much different than that reported for earlier transition matrices.

Pension Coverace. Pension coverage is closely but not perfectly linked with a more financially comfortable retirement and more loosely with eariy retirement. But pension coverage is not uniform across work environments. For exampie, it is well-known that pension coverage is much lower in parttime work situations, where part-time is defined in the usual manner of part-week work. But what of coverage across types of part-time work?

Beginning in 1977, a sumary question on the variety of fringe benefits available to the worker was asked periodically of members of the NLS Mature Women's cohort. Fortunately the fringe benefit question was asked in more or less identical form in each of the five year intervals following 1977. The question asks the respondent to identify from a flashcard the fringe benefits her employer makes available to her. Fox ail years except 198.9, one possibility is a "retirement program." In 2989 the response possibility was changed to a "retirement pension program." Detailed informarion on own pension coverage, including standard CPS pension coverage questions of the form Does your employer or union have a pension plan other than Social Security or Railroad Retirement benefits?" was collected for this cohort for the first time in 1979.) A comparison of the responses to the "retirement program" response to a standard CPS pension coverage question in the first five year interval year in which both questions were asked (1982) indicates a strong correspondence of the two questions. Of the respondents who answered YES to the CPS coverage question, all but 7 percent identified a "retirement plan" as one of the fringe benefits their employer offered. Of the respondents who answered No to the CPS question, only 8 percent identified a "retirement plan" as one of the fringe benefits their employer offered. See Table 18.

Tables 19 through 22 present pension coverage by work status for the survey years 1977, 1982, 1987, and 1989. The data for 1982 through 1989 include some not-employed respondents the fringe benefit questions are not limited to those currently working), but a more standard measure of pension coverage can be computed by dropping this group from the tabuiations. An important regularity of pension coverage by work structure emerges:

All statistics are weighted.
Although there are year-to-year fluctuations in pension coverage, especially in the smalier categories, the general pattern that emerges is one in which the most casual employees (PYR/PWK) have only one fourth the coverage of the full-time workers (FYR/FWK). More interesting, perhaps, the FYR/PWK workers have coverage only modestly higher than the $P Y R / P W K$ workers, 28 percent versus 22 percent. In contrast, the PYR/FWK workers have coverage rates that, while less than full-time workers, are double those of the other pyR categories. Apparentiy a full work week is the crucial pension eligibility factor. Of course pension coverage is quite distinct from pension receipt. A worker may leave the firm before her pension is vested. Many if not most of the part-year workers will have job separations that make chem ineiigible for pension payouts even though they are "covered" by a plan. In fact, of those respondents who were out of the labor force in 1989 , only 60 percent reported receipt of pension income in 1989, Table 23. Of course workers may be eligible for future payments, but not present ones, because many plans have age restrictions for payout. Pension receipt in 1989 rises to 72 percent for the oldest third of the sample, those who would be 62-66 years of age and eligible for pension payouts under most plans. Nonetheless low coverage rate for those who work a full-weeks but not full-hours is a source of concern, particularly given its growing incidence.

#### Abstract

The National Longitudinal Survey of Mature. Women provides a valuable data set for the investigation of recent trends in the structure of female work activity, including the growth of part-time work. It offers a quarter of a century of detailed information on approximately 5000 female respondents 30 to 44 years of age in the first year (1967), and provides an important opportunity to explore the dynamics of work choices from midlife to the eve of retirement for the entire sample and into the retirement period for a substantial subset of the sample during the time of this great transition.

Major findings of the analysis include:

1) The most obvious trend in work-time structure over the 1967-1989 period for the Mature women's cohort is the life cycle shift from no work to full-time (full-time weeks and full-time hours per week) and then back again. The percent of all respondents who work full-weeks and hours rises from 27 percent in 1967 to 40 percent in 1977 before falling to 28 percent in 1989. Conversely the percent not working at all falis from 48 percent in 1967 to 39 percent in 1982 before rising again to 49 percent in 1989: There is also a major shift out of part-year/fullweek work and into full-year/part-week work between 1967 and 1972 that persists persists throughout the sample period.
2) Among employed women, the most obvious phenomena in this data are i) the life cycle sensitivity of part-year work (the midiffe shift from part-year to filllyear work and return) ; and ii) the secular increase in full-year/part-week status, which doubles between 1967 and 1977 (to 19 percent of all employed respondents).
3) Large and sustained differences in work-time structure exist across industries--strong evidence that the employer's preferences are important. Manufacturing, for example, offers few part-time hours jobs. Ninety-three percent of all employees in that sector work full-time hours, though a significant share, 28 percent work less than forty weeks a year. This pattern is consistent with a great deal of specialized training and a relatively institutional work structure that admits little diversity. Conversely in the wholesale and retail sector, 35 percent of all employees work less than 35 hours a week; in the professional sector 26 percent; and in personal services 47 percent.
4) Part-year work appears to be driven by seasonal and cyclical factors. Industries such as agriculture and manufacturing have large numbers of employed female workers who usually worked full hours but for less than forty weeks in the year. Agriculture, wholesale and retail, personal services, and the entertainment industries have the greatest number of "casual" jobs, those with part-year and part-week employment. This no doubt reflects strong seasonal factors. Among the larger employment sectors, personal services and to a lesser extent wholesale and retail stand out as especially likely to offer part-time hours but fuil weeks.
5) At the individual level, the polar states-no work and full-time work-are quite stable over five year periods. Eighty percent of the nonworkers and two-thirds of the full-time workers were in the same state five years later. Among the various combinations of part-time states, part-year or part-week, only the fuli-year/part-week state was stable, with 40 percent of these found in the same state five years later. The other categories, especially casual work (part-year AND part-week), are transitory states, at least from a five year perspective. Only ten percent of the casual workers in the first period were casual workers five years later.
6) Casual work (part-time weeks and hours) would appear to be a stepping stone to more stable work commitments. Among casual workers in 1967, fifty percent were split more or less equally between full-year/partweek work and full-year/full-week work in 1972. About one-third were not working. Conversely two-thirds of the respondents who were in casual jobs in 1972 were out of the labor force five years earlier. Few full-year workers return to casual, part-year and part-week, work.
7) Marital disruption increases labor market activity. It is natural to imagine that the withdrawal of the husband from the labor force would have the same labor market effect on the spouse as a marital disruption since the family income effect is the same in both cases-loss of husband's earnings. Such is not the case. Not only is the rate of entry into full-time work not increased with the departure of the husband from the work force, it shrinks. The likelihood that a respondent who is married with spouse present will be working full-time in 1989 is cut in half if the husband is not in the labor force. The evidence is consistent with the hypothesis that this is due to greater home nursing demands on the woman.

Less work intensity in the pre-retirement years increases the early retirement rate. The average work withdrawal rate of the various parttime categories is twice that of full-time workers in the early retirement period. This is despite the limited pension coverage among part-time workers. Although there are significant year-to-year fluctuations in pension coverage, especially in the smaller work status categories, the general pattern is one in which the most casual employees (PYR/PWK) have only one fourth the coverage of the full-time workers (FYR/FWK). More interesting, perhaps, the FYR/PWK workers have coverage only modestly higher than the $\mathrm{PYR} / \mathrm{PWK}$ workers, 28 percent versus 22 percent. : In contrast, the PYR/FWK workers have coverage rates that, while less than full-time workers, are double those of the other

PYR categories. Apparently a full work week is the crucial pension eligibility factor.

1. Hanoch (1980a,b) and Blank (1988) are exceptions. These studies explore both the hours and weeks dimensions of the work decision. Both conclude that the two dimensions have quite distinct determinants.
2. As Blank (1990) recently remarked, "There is very little research on the dynamics of part-time work over a worker's lifetime." Blank (I990, p.142).
3. Blank (1989) reports that hours per week are quite stable over relatively short time intervals, e.g. a year.
4. Blank concludes, "Preliminary current work indicates that part-time work among adult women is only rarely used as a stepping stone between nonemployment and full-time employment, but is instead used as an alternative either to full-time employment or to nonemployment, Blank (1990, p.142).
5. Blank characterizes the results of two employer surveys as revealing that "the primary reason firms hire part-time workers is to resolve scheduling problems. Firms with high weekly and daily variance in workload were most likely to employ part-time workers." Blank (1990, p.143)
6. Blank (1988) presents evidence of the "simultaneity" of the hours and weeks decisions.
7. See also Hanoch (1980a,b) and Blank (1988).

# National Longitudinal Surveys (NLS) <br> Discussion Paper Series
